Chapter 1

OUTPUT

1.1 Overview

This section defines the output produced by CLOUDY. Each section begins with a sample of the output described, and then goes on to describe the meaning of the printout in greater detail. The output actually shown is from the Orion H II Region / PDR / molecular cloud test case (`orion_hii_pdr_pp.in`).

1.2 Header Information

Several lines of output echo the input commands and outline some properties of the initial continuum.

```
Cloudy 06.01.02

*****06Jan02*****

*****

```

This begins with the version number of CLOUDY, the date that the version was released, in the form yy.mm.dd. The following line gives this date in another form.

All of the input command lines, with the exception of those starting with a #, %, or *, are echoed before the calculation begins, and are saved to be reprinted after the calculation is completed.

```

```

This block of information describes the continuum that strikes the illuminated face of the cloud. The full block of information is shown above, and in the following discussion each line is given again just before it is described.

```

3198CellPeak1.00E+00  Lo 9.99e-09=912.21cm  Hi-Con:1.20E+02 Ryd  E(hi):7.35E+06Ryd  E(hi): 100.01 MeV

```

This gives the number of numerical frequency cells in the continuum followed by the energy (in Ryd) of the peak of hydrogen-ionizing continuum. This is the point with the largest flux density per unit energy interval (J_V). Next is the energy of the low-energy limit of the continuum, in both Ryd and cm. The last two numbers are the energies of the high-energy limit of the continuum in Ryd and MeV.

```

I(nu>1ryd): 2.4792  Average nu:1.382E+00  I( X-ray): -1.6194  I(BalC): 2.8255  Phi(BalMrC): 13.7081

```

This line gives the intensity or luminosity of the continuum source. Luminosities are printed if the inner radius of the cloud is specified. The units will be energy radiated by the central object into 4π sr [erg s^{-1}]. If an inner radius is not set then the code will compute the intensity case and give the emission per unit area of cloud surface. This is loosely called the intensity but is more formally $4\pi J$ where J is the proper mean intensity [$\text{erg cm}^{-2} \text{s}^{-1} \text{sr}^{-1}$ for an emission line; AGN3 Appendix 1].

The line gives the log of the energy ($\text{erg s}^{-1} \text{cm}^{-2}$ or erg s^{-1} , depending on whether it is the intensity or luminosity case) in the hydrogen-ionizing continuum ($1 \text{ Ryd} \leq h\nu < 100 \text{ MeV}$), and

the average energy of the hydrogen-ionizing continuum, in Ryd, weighted by photon number;

$$\langle h\nu \rangle = \frac{\int_{1 \text{ Ryd}}^{\infty} 4\pi J_{\nu} d\nu}{\int_{1 \text{ Ryd}}^{\infty} 4\pi J_{\nu}/h\nu d\nu} \quad [\text{Ryd}]. \quad (1.1)$$

The log of the energy in the X-ray continuum ($20.6 \text{ Ryd} \leq h\nu \leq 7676 \text{ Ryd}$) is followed by the log of the energy ($\text{erg s}^{-1} \text{ cm}^{-2}$ or erg s^{-1}) and the number of photons ($\text{cm}^{-2} \text{ s}^{-1}$ or s^{-1}) in the Balmer continuum (0.25 Ryd to 1.0 Ryd).

phi(1.0-1.8):12.9508 phi(1.8-4.0): 12.033 phi(4.0-20): 9.388 phi(20--): 7.634 Ion pht flx:1.001E+13

The third line gives the log of the number of photons ($\text{cm}^{-2} \text{ s}^{-1}$ or s^{-1}) in four frequency bins ($1.0 \text{ Ryd} \leq h\nu < 1.807 \text{ Ryd}$, $1.807 \text{ Ryd} \leq h\nu < 4.0 \text{ Ryd}$, $4.0 \text{ Ryd} \leq h\nu < 20.6 \text{ Ryd}$, and $20.6 \text{ Ryd} \leq h\nu < 7676 \text{ Ryd}$). The last number “Ion pht flx” is the flux of hydrogen ionizing photons;

$$\Phi(H^0) = \frac{Q(H^0)}{4\pi r^2} \quad [\text{cm}^{-2} \text{s}^{-1}]. \quad (1.2)$$

In this equation $Q(H^0)$ is the total number of hydrogen-ionizing photons emitted by the central object (s^{-1}), and r is the separation between the center of the central object and the illuminated face of the cloud. Unlike the majority of the quantities printed in the header, $\Phi(H^0)$ (per unit area) is always printed, never $Q(H^0)$ (into $4\pi \text{ sr}$).

I(gam ray): 0.0000 phi(gam r): 0.0000 I(Infred): 1.5064 Alf(ox): 0.0000 Total inten: 3.0012

The fourth line of the header gives some information about the low and high energy portions of the incident continuum. The first number is the log of the luminosity or intensity in the gamma-ray ($\sim 100 \text{ keV}$ to $\sim 100 \text{ MeV}$) continuum. The second number is the log of the number of photons over this energy range. The third number is the log of the luminosity in the continuum between 0.25 Ryd and the lowest energy considered, presently an energy of $3.040 \times 10^{-9} \text{ Ryd}$. All of these entries are either per unit area, or radiated into $4\pi \text{ sr}$, depending on whether the intensity or luminosity case was specified.

The entry “Alf(ox)” is the spectral index α_{ox} , defined as in Zamorani et al. (1981), except for the difference in sign convention. This is the spectral index which would describe the continuum between 2 keV (147 Ryd) and 2500 \AA (0.3645 Ryd) if the continuum could be described as a single power-law, that is,

$$\frac{f_{\nu}(2 \text{ keV})}{f_{\nu}(2500 \text{ \AA})} = \left(\frac{\nu_{2 \text{ keV}}}{\nu_{2500 \text{ \AA}}} \right)^{\alpha} = 403.3^{\alpha}. \quad (1.3)$$

The definition of α_{ox} used here is slightly different from that of Zamorani et al. since implicit negative signs are *never* used by CLOUDY. Typical AGN have $\alpha_{ox} \sim -1.4$. If no X-rays are present then $\alpha_{ox} = 0$. The last number on the line is the log of the total energy in the continuum between $3.040 \times 10^{-9} \text{ Ryd}$ and 100 MeV .

log L/Lsun: 3.9743 Abs bol mg: -5.1858 Abs V mag: 2.4170 Bol cor: -7.6028 nuFnu(Bbet): 34.5867

This line is optional, depending on whether the luminosity or intensity case is specified. (It was not printed in this model since we are working in the intensity case but a sample is shown). This is printed in the luminosity case. First comes the log of the total luminosity in the continuum in solar units. The absolute bolometric magnitude, absolute V magnitude, and the bolometric correction, are then given, followed by the log of the continuum specific luminosity [$\nu F_{\nu}(H\beta)$] at the wavelength of $H\beta$ [erg s^{-1}].

U(1.0----):3.339E-02 U(4.0----):8.293E-06 T(En-Den):4.586E+01 T(Comp):3.532E+04 nuJnu(912A):5.422E+02

This line begins with two ionization parameters. The first is the dimensionless ratio of ionizing photon to hydrogen densities, defined as

$$U \equiv \frac{\Phi(H^0)}{n_H c}, \quad (1.4)$$

where n_H is the total hydrogen density. The second number is defined in a similar way, but the numerator is the number of photons with energies greater than 4 Ryd (i.e., helium-ionizing). The third number is the equivalent black-body temperature corresponding to the energy density u at the illuminated face of the cloud, from the incident continuum and Stefan's radiation density constant a ;

$$T_u \equiv (L/4\pi r^2 ac)^{1/4} \quad [\text{K}]. \quad (1.5)$$

$T(\text{Comp})$ is the Compton temperature of the incident radiation field.¹ The last number is $4\pi\nu J_\nu(912\text{\AA})$, the flux at 912\AA ($\text{erg cm}^{-2} \text{s}^{-1}$), where J_ν is the mean intensity of the incident continuum (Mihalas, 1978).

Occ(FarIR):2.911E+08 Occ(H n=6):1.326E-11 Occ(1Ryd):2.470E-14 Occ(4R):5.400E-20 Occ(Nu-hi):1.201E-32
Tbr(FarIR):4.835E+05 Tbr(H n=6):5.816E-08 Tbr(1Ryd):3.905E-09 Tbr(4R):3.413E-14 Tbr(Nu-hi):2.269E-25

These lines give dimensionless photon occupation numbers $\eta(\nu)$, for the incident continuum at several energies. The occupation number is defined as

$$\eta_\nu \equiv J_\nu(\nu) \left(\frac{2h\nu^3}{c^2} \right)^{-1}, \quad (1.6)$$

and the incident continuum brightness temperature $T_b(\nu)$, [K] is defined as

$$T_b(\nu) \equiv J_\nu(\nu) \left(\frac{2k\nu^2}{c^2} \right)^{-1} \quad [\text{K}]. \quad (1.7)$$

These energies correspond to the lowest frequency considered (presently 10 MHz); the ionization potential of the $n = 6$ level of hydrogen (1/36 Ryd); one Rydberg; four Rydbergs, and the high-energy limit of the incident continuum. The energy where the last number is evaluated depends on the continuum shape. The energy is given by the fifth number on the first line of the continuum output.

1.3 Chemical composition

Gas Phase Chemical Composition
H : 0.0000 He: -1.0159 Li: -9.4456 Be: -10.7418 B : -10.0360 C : -3.9385 N : -4.1002 O : -3.4622 F : -7.9927
Ne: -4.0501 Na: -6.3298 Mg: -5.0788 Al: -7.4597 Si: -5.9133 P : -7.0617 S : -4.7399 Cl: -7.0675 Ar: -5.3799
K : -7.3439 Ca: -9.5901 Sc: -11.1518 Ti: -9.0969 V : -10.1537 Cr: -8.5017 Mn: -7.7212 Fe: -6.4597 Co: -9.0200
Ni: -7.7100 Cu: -8.6596 Zn: -7.9022

¹For a blackbody radiation field T_{Compton} is roughly 4% lower than the blackbody color temperature T_{color} when the energy density temperature T_u is $> T_{\text{color}}$. Only when $T_u \equiv T_{\text{color}}$ does induced Compton heating cause $T_{\text{Compton}} \equiv T_{\text{color}}$. If $T_u > T_{\text{color}}$ then $T_{\text{Compton}} > T_{\text{color}}$ because of induced Compton heating. All of the relevant physics is included in the Compton temperature printed here.

```

Grain Chemical Composition
C : -3.5553 O : -3.8821 Mg: -4.4841 Si: -4.4841 Fe: -4.4841
Sum Atoms Depleted: -3.2828
Depletion/Grains-1: 2.65%

Number of grains per hydrogen
Carbonaceous: -14.166 silicate: -14.103

```

The chemical composition of the cloud comes next. The three blocks of numbers give the gas-phase abundances of the elements, the abundances contained in grains, and the number of each type of grains per unit hydrogen. The numbers are the logs of the number densities of the elements, relative to the gas-phase hydrogen abundance of unity (so, 0 on the log scale). The sum of all atoms depleted with the **metals deplete** command is given in Sum Atoms Depleted. This is not guaranteed to agree with the atoms depleted with **grains** command. The percent offset is reported in Depletion/Grains-1. Only the active elements are included (those turned off with the **elements off** command are not printed). If grains are not present then the second two blocks are not printed.

1.4 Comments before or during the calculation

The code may print comments as the calculation proceeds. These are printed with the start of the comment in capital letters to make them easy to find with a script. The comments fall into three categories:

DISASTER something has unexpectedly caused the calculation to stop. The results are bogus and should not be trusted. The code should immediately return to the calling program.

PROBLEM something did not go as expected but the calculation is continuing. This might be a convergence failure at a point in the cloud. This is an indication that the code was having difficulties and a few of these can occur in a normal set of calculations. The predictions can be used if only a few occur and if the comments at the end of the calculation (see page 9 below) do not identify other problems.

NOTE this gives advice about the calculation. These can be ignored if you prefer.

1.5 Zone Results

Next comes a summary of the conditions in the first and last zone. This print out is done in routine *PrtZone* which should be consulted if there are any questions. The following is the output produced for one zone. Details follow.

```

The results of calculations for the first and last zones are always printed. Results for intermediate zones can be printed if desired (see the **print every** command). The following is a line-by-line description of the output produced for each printed zone.

```
##### 1 Te:9.361E+03 Hden:1.000E+04 Ne:1.101E+04 R:1.000E+30 R-R0:5.223E+11 dR:1.045E+12 NTR: 3 Htot:3.461E-16 T912: 1.48e-05###
```

The line begins with a series of ##### characters to make it easy to locate with an editor. The zone number is the first number and it is followed by the electron temperature of the zone (“Te”). A lower case “u” will appear before the “Te” if the temperature solution is possibly thermally unstable. This occurs when the derivative of the net cooling with respect to temperature is negative. This is discussed further in the section on thermal stability problems starting on page 109 below. The total hydrogen (“Hden”) and electron (“Ne”) densities (cm^{-3}) follow. The next number (“R”) is the distance from the center of the central object to the center of the zone. The depth, the distance between the illuminated face of the cloud and the center of the zone, (“R-R0”, or “r-r⁰”), and the thickness of the zone (“dR”, or δr), (all are in cm), follow. The inner edge of the zone is $(r - r_o) - \delta r/2$ from the illuminated face of the cloud. The line ends with a number indicating how many ionization iterations were needed for this zone to converge (NTR), followed by the total heating² (“Htot”; photoelectric and otherwise, $\text{erg cm}^{-3} \text{ s}^{-1}$), and the optical depth between the *illuminated* face of the cloud and the *outer* edge of the zone at the Lyman limit (T912; the number is the *total absorption* optical depth at 912Å, and not the hydrogen Lyman-limit optical depth).

```
WIND; V:-7.000e+00km/s G:-0.00e+00 Accel: 8.62e-06 Fr(cont): 1.000 Fr(line): 0.000 Fr(dP): 0.000
```

A line describing the velocity and acceleration of the zone is printed if the cloud is a wind. The numbers are the wind velocity at the outer edge of the current zone (km s^{-1}), inward gravitational acceleration (cm s^{-2}), total outward radiative acceleration (cm s^{-2}), and the fraction of this acceleration caused by the incident continuum, line driving, and the gradient of the radiation pressure.

²CLOUDY defines heating as the energy input by the freed photoelectron, or $h\nu - \text{IP}$, where IP is the ionization potential of the atom or ion, and $h\nu$ is the energy of the photon. See AGN3 for more details.

```
P(Lines):(Mg 2 2796A 0.32) (Mg 2 2803A 0.20) (H 1 6563A 0.13) (H 1 1.875m 0.10) (Fe 2 1786A 0.06) (H 1 4861A 0.05)
```

A line describing the source of the radiation pressure is generated if the ratio of line radiation to gas pressure, P_{rad}/P_{gas} , is greater than 5%. The line begins with the label “P(Lines)” and continues with the fraction of the total radiation pressure produced by that emission line, the spectroscopic designation of the line, and its wavelength. Up to twenty lines can be printed, although in most cases only $L\alpha$ and a few others will dominate.

```

```

The line begins with the ratios $n(H^0)/n(H_{tot})$ and $n(H^+)/n(H_{tot})$ where H_{tot} is the total density in H all forms (including molecular). If **print h-like departure coefficients** has been specified then departure coefficients are also printed on the following line. Neutral hydrogen H^0 is defined to be the total population of atomic hydrogen in all explicitly computed bound levels. Next comes “H+o/Hden”, the ratio $[n(H^0) + n(H^+)]/n(H_{tot})$.

The following five numbers give densities of the negative hydrogen ion and several molecules (H^- , H_2 , H_2^+ , and HeH^+) relative to the total hydrogen density. Note that, with this definition of the hydrogen density, a fully molecular gas will have $n(H_2)/n(H) = 0.5$. These molecular abundances are also expressed as departure coefficients if the **print departure coefficients** command occurs. The last number is the H^0 and H^+ column densities (cm^{-2}).

The next line gives very similar information for deuterium.

```

```

This information is only printed if the **print H-like populations** command occurs. The numbers give the populations of the H^0 levels relative to the ionized hydrogen density. All of these populations usually are relative to the ionized hydrogen density, but can also be printed as LTE departure coefficients if the **print departure coefficients** command is given.

```
Helium        6.57e-04 9.45e-01 5.47e-02 He I2SP3 3.52e-06 Comp H,C 1.75e-22 4.64e-23 Fill Fac 1.00e+00 Gam1/tot 1.00e+00
```

The first three numbers are the total populations of the three ionization stages of helium relative to the total helium abundance. The population of atomic helium is the sum of the total population in the triplets and singlets, including the population of all explicitly computed levels of each. These populations can also be expressed as departure coefficients if this option is set with the **print departure coefficients** command. The population of $He\ 2^3S$, relative to the total helium abundance, follows. The Compton heating and cooling rates (both $erg\ cm^{-3}\ s^{-1}$) are next, followed by the gas filling factor. The last number is the fraction of the total hydrogen ionizations that are caused by photoionization from the ground state.

```
He singlet n 6.54e-04 2.35e-11 6.59e-18 2.09e-18 3.18e-18 2.52e-18 He tripl 3.52e-06 9.32e-16 7.41e-18 4.77e-17 7.56e-18
```

The first numbers are the level populations of the l -levels within $n = 1$ to 3 of the He^0 singlets. The next group consists of He^0 triplet populations of $2S$, the three 2^3P_j levels and the $3S$, $3P$, and $3D$ levels. All populations are relative to the total helium abundance. Departure coefficients are also printed if requested.

```

```

Some information concerning the pressure is printed. The gas equation of state includes thermal gas pressure, the radiation pressure due to trapped line emission, magnetic and turbulent pressure, and the radiation pressure due to absorption of the incident continuum. The first number is the gas pressure $n_{gas} T_{gas}$ (with units $\text{cm}^{-3} \text{ K}$), followed by the total pressure (dynes cm^{-2}), and is followed by the gas pressure ($n_{gas} k T_{gas}$) in dynes cm^{-2} . The radiation pressure follows. The second to last number is the radiative acceleration (cm s^{-2}) at the inner edge of this zone. The radiative acceleration is computed with all continuous scattering and absorption opacities included. The last number is a force multiplier, defined as in [Tarter and McKee \(1973\)](#), and is the ratio of total opacity to electron scattering opacity.

The second line gives more information. The line starts with “Texc(La)”, the excitation temperature T_{exc} of $L\alpha$, defined as

$$\frac{n(2p)/g(2p)}{n(1s)/g(1s)} = \exp[-h\nu/kT_{exc}(L\alpha)]. \quad (1.8)$$

This is followed by the temperature corresponding to the energy density of the attenuated incident continuum (“T(contn)”) and the diffuse continua (“T(diffs)”). This includes all trapped lines and diffuse continuous emission. The entry “nT (c+d)” is the energy density of the sum of these two continua expressed as an equivalent pressure nT [$\text{cm}^{-3} \text{ K}$]. The line ends with the ratios of the radiation to gas pressure “Prad/Gas” and the ratio of magnetic to gas pressure “Pmag/Gas”.

```

Some properties of the grain populations are printed if they are present. Each line gives the results of calculations for a specific type and size of grain. Graphite and silicate are normally included when grains are present. Each line begins with the name of the grain and an asterisk appears if quantum heating was important for the species. Quantum heating is only computed if it is significant due to its computational expense. The remainder of the line gives the equilibrium temperature of the grain, the potential in volts, the charge, the drift velocity, the gas heating ($\text{erg cm}^{-3} \text{ s}^{-1}$) due to grain electron photoemission, and the dimensionless fraction of the total gas heating due to grain electron photoemission. For quantum-heated grains the temperature is the average weighted by T^4 .

```
Molecules      CH/Ctot: 3.65e-04 CH+/Ctot 5.82e-13 CO/Ctot: 5.52e-01 CO+/Ctot 1.95e-14 H2O/Otot 3.27e-09 OH/Otot1 4.18e-11
```

A line giving relative abundances of some molecules is printed if the molecular fraction is significant. All molecular abundances are relative to either the total carbon or total oxygen abundance (this is indicated in the label for each). In order, the molecules are CH, CH⁺, CO, CO⁺, H₂O, and OH.

```
Lithium      8.94e-02 9.11e-01 9.53e-10 0.00e+00 Berylliu 9.99e-01 6.40e-04 6.38e-05 7.06e-10 0.00e+00 sec ion: 7.66e-15
```

Abundances of each stage of ionization of lithium and beryllium relative to the total gas-phase abundance of the element are followed by the suprathermal secondary ionization rate [s\$^{-1}\$].

```
{\setverbatimfontsize{\tiny}
```

```
\begin{verbatim}
```

```
Carbon      6.76e-07 1.91e-02 9.70e-01 1.10e-02 1.77e-04 2.36e-09 0.00e+00 H2O+/O 0.00e+00 OH+/Otot 0.00e+00 Hex(tot) 0.00e+00
```

The abundances of the seven stages of ionization of carbon relative to the total gas-phase carbon abundance begin the line. The abundance of H₂O⁺ and OH⁺ relative to the total gas-phase oxygen abundance are given. These are followed by “Hex(tot)”, the extra heat (erg cm⁻³ s⁻¹) due to fast neutrons, dissipation of turbulence, or added with the **hextra** command.

```
Nitrogen     1.60e-06 1.72e-02 9.69e-01 1.41e-02 4.77e-05 1.34e-07 9.81e-14 0.00e+00 O2/Otot1 0.00e+00 O2+/Otot 0.00e+00
```

The relative populations of the eight ionization stages of nitrogen are printed first. The abundance of O₂ and O₂⁺, relative to the total oxygen abundance, follows.

```

There are too many ionization stages to print across the line for elements more massive than neon. Although all stages with non-trivial abundances are computed, only the highest twelve stages of ionization are printed. The first number is an integer indicating how many stages are “off the page to the left”. If the number is 2, then the first printed stage of ionization is twice ionized, i.e., Fe⁺².

1.6 Comments after the calculation

```
the Orion HII Region / PDR / Molecular cloud with an open geometry
Calculation stopped because outer radius reached. Iteration 1 of 2
```

A series of messages appear after the printout of the last zone. The first will say why the calculation stopped. In a valid calculation the model will stop because one of the specified stopping criteria specified was met. If no other criteria are specified then the calculation usually stops when the default lowest temperature of 4000 K is reached. If the code stops because of an unintended reason (i.e., internal errors, or reaching the default limit to the number of zones) then a warning is printed saying that the calculation may have halted prematurely.

Only one stopping criterion message will be printed. The possible messages, and their interpretations, are:

...**because of radiation pressure** By default a cloud will have constant density. CLOUDY will keep the total pressure, particle and radiation, constant if constant pressure is specified with the **constant pressure** command. The radiation pressure is small at the boundaries of the cloud, so the cloud will be unstable if the ratio of radiation to total pressure exceeds 0.5. The calculation stops, and this message is generated, if $P_{rad}/P_{tot} > 0.5$ occurs after the first iteration.

- ... **because lowest EDEN reached** The calculation can be forced to stop when the electron density (**eden**) falls below the value set by the **stop eden** command. This can be used to stop the calculation at an ionization front. The default lowest electron density is negative, so this stopping criterion occurs only when the command is entered.

- ... **because low electron fraction** The calculation can be forced to stop when the ratio of electron to hydrogen densities falls below a certain value, as set by the **stop efrac** command. This can be used to stop the calculation at an ionization front when the hydrogen density there is not known (for instance, in a constant pressure model). The default lowest electron density is negative, so this stopping criterion applies only when the command is entered.

- ... **because large H₂/H fraction** The calculation can be forced to stop when the ratio of densities of molecular hydrogen to total hydrogen rises above the value set by the **stop mfrac** command. The molecular fraction is defined as $2n(\text{H}_2)/n(\text{H}_{\text{tot}})$. This can be used to stop the calculation at some depth into a PDR. The default highest molecular density is $\gg 1$, so this stopping criterion occurs only when the **stop mfrac** command is entered.

- ... **because wind veloc too small** The code can perform a wind calculation which includes the outward force due to radiation pressure and the inward force of gravity. This message is printed if the gas decelerates to a stop.

- ... **because code returned BUSTED** The calculation stopped because something bad happened. Please post the input script and version number on the discussion board.

- ... **because DRAD small - set DRMIN** The Strömgren radius of the H⁺ zone is estimated at the start of the calculation and the smallest allowed zone thickness is set to a very small fraction of this. The calculation will stop if the zone thickness falls below this smallest thickness. This can occur because of any of several logical errors within CLOUDY (adaptive logic is used to continuously adjust the zone thickness), although it can rarely occur for physical reasons as well. The smallest thickness can be reset to any number with the set **drmin** command but it should not be necessary to do this. Please post the input script and version number on the discussion board.

- ... **because DR small rel to thick** The depth into the cloud is stored as the double precision variable *depth* and the zone thickness is stored as the double precision variable *drad*. If the zone size becomes too small relative to the depth ($drad/depth < 10^{-14}$) then the depth variable will underflow such that $depth + drad = depth$. The calculation will stop if this problem prevents the density from being properly evaluated.

- ... **because optical depth reached** The largest allowed continuous absorption optical depth can be set with the **stop optical depth** command. The command specifies both the absorption optical depth, and the energy at which it is to be evaluated. Scattering opacities are not included since their effects are very geometry dependent. If the calculation stops because the largest continuum optical depth is reached, then this line is printed. This line is also printed if the **stop effective column density** command is used to stop the calculation, since this command is actually a form of the **stop optical depth** command.

- ...**because outer radius reached** The default outer radius is unphysically large, but can be changed with the **radius** or **stop thickness** commands. If the calculation stops because the outer radius set by one of these commands is reached, then this line is printed.
- because column dens reached** a limit to the largest allowed neutral, ionized, and total hydrogen column densities is set with the **stop column density**, **stop neutral column density**, or **stop ionized column density** commands. This message will be printed if one of these criteria stops the calculation.
- ...**because lowest Te reached** The default value of the lowest temperature allowed is 4000 K. This is reasonable when only emission from warm ionized gas is of interest. The limit can be changed with the **stop temperature** command. This message is printed if the calculation stops because the lowest temperature is reached.
- ...**because highest Te reached** The default value of the highest temperature allowed is 1.001×10^{10} K. The limit can be changed with the **stop temperature exceeds** command. This message is printed if the calculation stops because the highest allowed temperature is exceeded.
- ...**because freeze out fraction** Nick Abel incorporated the condensation of molecules onto grain surfaces. Currently CO, H₂O, and OH condensation are treated. The chemistry network will become unstable when oxygen is highly depleted from the gas phase. By default the code stops when 99% of the oxygen abundance has condensed out of the gas phase.
- ...**because NZONE reached** By default the code will stop after computing 1400 zones. This can be reset with the **stop zone** command. This message is printed if the calculation stops because the limiting number of zones is reached. A warning is printed at the end of the calculation since this was probably not intended.
- The default limit to the number of zones can be increased, while retaining the check that the default limit is not hit, by using the **set nend** command.
- ...**because volume too large for this cpu** This indicates that the effective volume of the last zone was too large to be represented as a single precision floating point number. This happens when R/R_{in} becomes really large. Usually this indicates that none of the intended stopping criteria were hit, so you should check those. If you really intend for the simulation to integrate this far, you should increase the inner radius.
- ...**because line ratio reached** It is possible to set a limit to the largest value of an emission-line intensity ratio with the **stop line** command. This message is printed if the calculation stops because the largest value of the ratio is reached.
- ...**because internal error - DRAD** An internal logical error caused this message to be printed. Please report the problem, including the command lines and the version number of CLOUDY, on the discussion board at the code's web site, .
- ...**because initial conditions out of bounds** The temperature of the first zone was not within the temperature bounds of the code. This is probably due to the incident continuum not being set properly.

- ...**because zero electron density** The electron density fell to zero because there was no source of ionization. This is unphysical and usually occurs because the cloud boundary conditions were not set properly. Consider adding at least galactic background cosmic rays with the **cosmic ray background** command and perhaps the galactic or extragalactic background.
- ...**because reason not specified** This is an internal error. Please post the input and version number on the code's discussion board.

1.7 Geometry

The geometry is plane-parallel.

The code will next say whether the geometry is plane parallel ($\Delta r/r_0 < 0.1$), a thick shell ($\Delta r/r_0 < 3$), or spherical ($\Delta r/r_0 \geq 3$), where r_0 is the inner radius and Δr is the thickness of the cloud.

1.8 Warnings, Cautions, Surprises, and Notes

```
C-Cloud thicker than smallest Jeans length=3.51e+16cm; stability problems? (smallest Jeans mass=2.58e-01Mo)
!Magnetic field & cosmic rays both present. Their interactions are not treated.
!Some input lines contained underscores, these were changed to spaces.
!Suprathermal collisional ionization of H reached 83.84% of the local H ionization rate.
!H2 vib deexec heating reached 6.68% of the local heating.
!Charge transfer ionization of H reached 95.8% of the local H ionization rate.
!The largest continuum brightness temperature was 4.835e+05K at 1.052e-08 Ryd.
!Both constant pressure and turbulence makes no physical sense???
!AGE: Cloud age was not set. Longest timescale was 8.43e+15 s = 2.67e+08 years.
!The excitation temp of Ly $\alpha$  exceeded the electron temp, largest value was 4.60e+03K (gas temp there was 1.01e+03K, zone 310)
!Line absorption heating reached 13.45% of the local heating - largest by level 1 line Si 2 34.8m
!Some infrared fine structure lines are optically thick: largest tau was 2.05e+03
!Local grain-gas photoelectric heating rate reached 98.8% of the total.
!The local H2 photodissociation heating rate reached 12.8% of the total heating.
!The CMB was not included. This is added with the CMB command.
!The fraction of H in H2 reached 100.0% at some point in the cloud.

!The fraction of O in H2Ogrn reached 58.3% at some point in the cloud.
!A significant amount of molecules condensed onto grain surfaces.
!These are the molecular species with "grn" above.
!The optical depth in the H I 21 cm line is 6.84e-01
!The optical depth in the 12CO J=1-0 line is 2.79e+05
!The radiation pressure jumped by 123% at zone 334, from 5.28e-11 to 3.67e-11 to 3.73e-11
!The H2 density varied by 12.6% between two zones
Continuum fluorescent production of H-beta was significant.
Te-ne bounds of Case B lookup table exceeded, H I Case B line intensities set to zero.
Te-ne bounds of Case B lookup table exceeded, He II Case B line intensities set to zero.
Destruction of He 2TriS reached 3.4% of the total He0 dest rate at zone 236, 3.4% of that was photoionization.
Critical density for l-mixing of He I not reached. More resolved levels are needed for accurate He I line ratios.
The largest continuum occupation number was 2.911e+08 at 1.052e-08 Ryd.
The continuum occupation number fell below 1 at 1.944e+04 microns.
The continuum brightness temperature fell below 10000K at 1.433e+06 microns.
Ratio of computed diffuse emission to case B reached 2.30168 for iso 1 element 2
Global grain photoelectric heating of gas was 9.9% of the total.
Local grain-gas cooling of gas rate reached 90.4% of the total.
The local H2 cooling rate reached 7.2% of the local cooling.
Local CO rotation cooling reached 83.0% of the local cooling.
The Balmer continuum optical depth was 3.68e+03.
The Balmer continuum stimulated emission correction to optical depths reached 7.64e-02.
The Paschen continuum optical depth was 1.69e+03.
The continuum optical depth at the lowest energy considered (1.052e-08 Ryd) was 3.213e+03.
The optical depth to Rayleigh scattering at 1300A is 4.36e-02
3 body rec coef outside range 1
The fraction of Cl in CCl+ reached 0.103% at some point in the cloud.
The fraction of N in HNC reached 0.312% at some point in the cloud.
The fraction of C in C2H reached 2.60% at some point in the cloud.
The fraction of C in COgrn reached 0.379% at some point in the cloud.
```

The next messages fall into four categories: warnings beginning with “W-”; cautions beginning with “C-”; surprising results beginning with an explanation mark (“!”), and notes.

CLOUDY does many internal sanity checks to confirm that its range of validity was not exceeded (Ferland, 2001a). Warnings are issued to indicate that the program has not treated an important process correctly. For instance, warnings occur if the temperature was high enough for the electrons to be relativistic, if the global heating - cooling balance is off by more than 20%, or if the code stopped for an unintended reason. We would like to hear about warnings - the web site has a discussion board to place comments. Cautions are less severe, and indicate that CLOUDY is on thin ice. Examples are when the optical depths in excited states of hydrogen change during the last iteration. Surprises indicate that, while the physical process has been treated correctly, the result is surprising. An example is when induced Compton heating is more that 5 percent of the total Compton heating. Notes indicate interesting features about the model, such as maser effects in lines or continua, or if the fine structure lines are optically thick. The messages are usually self-explanatory.

1.9 Optional Plot

If any of the optional plots are requested with a **plot - -** command then they will appear next. This option is seldom used today since it is much easier to create data files with save commands and then use other software to make plots.

The final printout begins by reprinting the input commands. The box surrounding it gives both the version number of CLOUDY (at the top) and the log of the ionization parameter (the ratio of ionizing photon to hydrogen densities) at the bottom.

```

Emission Line Spectrum. Constant Pressure Model. Open geometry. Iteration 2 of 2.
Intensity (erg/s/cm^2)

```

This line summarizes some properties of the model and output. The first part indicates whether the energy in the emission lines is given as the luminosity case (the energy radiated by a spherical shell covering Ω sr [erg s⁻¹] where $\Omega/4\pi$ is the covering factor) or the intensity case (emission produced by a unit area of gas [erg s⁻¹ cm⁻²]). Which of the two choices is printed is determined by whether the luminosity of the continuum was specified as the luminosity radiated by the central object into 4π sr or the intensity ($4\pi J$) of the incident continuum (erg cm⁻² s⁻¹) at the illuminated face of the cloud. If the cloud is spherical and the intensity case is computed then the emergent emission-line spectrum will be per unit area in units of the inner radius r_0 (that is, the total line luminosity radiated by a shell covering 4π sr will be the listed intensity $4\pi J \times 4\pi r_0^2$). The second part of this line indicates the density structure (i.e., wind, constant density, constant pressure, constant gas pressure, power-law density distribution, etc). The next section tells whether the geometry was open or closed (these are defined in Part I of this document). The last part indicates the iteration number.

A series of predicted quantities follow. These are mainly emission-line intensities although the output also includes other predicted quantities.

Some continua and various indications of contributors to lines and continua are included. The Chapter of this document describing observed quantities (starting on page 25) tells how to convert these into some observed quantities. Not all are printed by default. The discussions on the **print** commands in Part I tell how to get more or fewer predictions. This list of emission lines can also be sorted by wavelength or intensity, and can be printed as a single column so that they can be entered into a spreadsheet.

The organization and meaning of the different of lines in the printout is discussed in the Chapter *The Emission Lines* starting on page 95.

A list of emission lines with negative relative intensities may follow the main block of lines. These are lines which heat rather than cool the gas (heating is negative cooling). This is not a problem but occurs if the line's collisional de-excitation rate exceeds its collisional excitation rate. This usually occurs when the line is radiatively excited but collisionally de-excited.

1.10.1 Intrinsic line intensities and luminosities

There are two blocks of predicted intensities. The block “Intrinsic line intensities” is the intrinsic emission from the cloud. The intrinsic emission includes all processes that affect the line formation and transfer. This includes collisional processes, fluorescence, line destruction by background opacities such as dust or the Lyman continuum of hydrogen, and recombination. The intrinsic intensities do not include the effects of absorbers or scatters that do not lie within the line-formation region.

1.10.2 Emergent line intensities and luminosities

The block “Emergent line intensities” is the emission observed from outside the cloud. In an open geometry the inward part of the line includes the effects of extinction between the line-forming region and the illuminated face. There is an additional contribution due to reflection off the gas in the outward direction. The outward part of the line includes the effects of extinction between the shielded face and the point where the line forms. In a closed geometry the emergent intensity is the emission escaping to the outer edge of the slab. All of this is very geometry dependent. For an open geometry, in particular, the observed emission will depend strongly upon the viewing angle.

If the intrinsic and emergent values are very different then it is important to understand the geometry and what is actually observed. This is an indication of the uncertainty if the predictions have a strong geometry dependence.

The following is an example of the emission-line output. The first column indicates the species and the second is the wavelength. “A” indicates Angstroms and “m” indicates microns. The third column is the log of the intensity [$\text{erg cm}^{-2} \text{s}^{-1}$] or luminosity [erg s^{-1}] depending on which case was used. The last column is the intensity of the line relative to the normalization line, $H\beta$ by default.

1.10.3 Air vs vacuum wavelengths

The emission line wavelengths follow the convention that vacuum wavelengths are used for $\lambda < 2000\text{\AA}$ and STP air wavelengths are used for $\lambda \geq 2000\text{\AA}$. The **print line vacuum** command tells the code use vacuum wavelengths throughout. The continuum is always reported in vacuum wavelengths to avoid a discontinuity at 2000\AA .

1.10.4 Some physical properties of the cloud

```
the Orion HII Region / PDR / Molecular cloud with an open geometry
Cooling:  HFBc    0 :0.110 HFFc    0 :0.077 TOTL  3727A:0.074 O  3  5007A:0.210 O  3  4959A:0.070 S  3  9532A:0.074
Heating:  BFH1    0 :0.817 BFHe    0 :0.074 GrGH    0 :0.099
```

Cooling: This line indicates the fraction of the total cooling (defined here as the energy of the freed photoelectron, see AGN3 Chapter 3) carried by the indicated emission lines. The line label is followed by the ratio of the energy in the line to the total cooling. This is an important indication of the fundamental power-losses governing conditions in the model. The labels used are the same as those in the line array.

Heating: This line indicates the fraction of the total heating produced by various processes. The format is the same as the line giving the cooling.

```
IONIZE PARMET:  U(1-) -1.4764  U(4-): -5.0813  U(sp): -4.46  Q(ion):  -4.574  L(ion)-13.505  Q(low): 15.158  L(low) 1.121
```

The line begins with the log of the H “U(1-)” and He⁺ “U(4-)” ionization parameters. The third number “U(sp)” is the log of a spherical ionization parameter often used in spherical geometries, such as H II regions or planetary nebulae. It is defined as

$$U_{sph} = \frac{Q(H^0)}{4\pi R_s^2 n_{HC}} \quad (1.9)$$

where R_s is the Strömberg radius, defined as the point where the hydrogen neutral fraction falls to $H^0/H = 0.5$. If no ionization front is present then U_{sph} is evaluated at the outer edge of the cloud. The next two numbers are the log of the number of hydrogen-ionizing photons ($h\nu \geq 1$ Ryd) exiting the nebula “Q(ion)” and the log of the energy in this continuum “L(ion)”. The next two

numbers are the equivalent quantities for non-ionizing ($h\nu < 1$ Ryd) radiation. These are either per unit area or by a shell covering 4π sr. These have been corrected for the r^{-2} dilution if per unit area, and so are directly comparable with the numbers given at the start of the calculation.

```
ENERGY BUDGET:  Heat:   1.725  Coolg:   1.725  Error:   0.0%  Rec Lin:   1.462  F-F  H -5.612  P(rad/tot)mx:1.10E-01  R(F Con):1.737e+05
```

This line gives an indication of the energy budget of the nebula. The first number “Heat” is the log of the total heating (in ergs s^{-1} , but again either into 4π sr or cm^{-2}). The second number “Coolg” is the log of the total cooling, in the same units. Cooling is the total energy in collisionally excited lines and part of the recombination energy, but *does not* include recombination lines (AGN3 Chapter 3). The percentage error in the heating-cooling - cooling match “Error” follows. The next numbers give “Rec Lin”, the log of the total luminosity in recombination lines, “F-F H”, the log of the amount of energy deposited by free-free heating, and “P(rad/tot)mx”, the largest value of the ratio of radiation to gas pressures that occurred. The line ends with **R(F Con)**, the resolving power in the fine continuum.

```
Col(Heff):      1.031E+25  snd travl time  5.06E+13 sec  Te-low: 1.69E+01  Te-hi: 1.08E+04  G0TH85:3.54E+05  G0DB96:4.54E+05
```

The effective column density “Col(Heff)”, as defined in the section in Part 1 on the **stop effective column density** command, is printed. This is followed by “snd travl time”, the sound travel time across the nebula in seconds. Constant pressure is only valid if the cloud is static for times considerably longer than this. The last two numbers are the lowest “Te-low” and highest “Te-hi” electron kinetic temperatures found in the computed structure. The last numbers “G0TH85” and “GHBD96” give the intensity of the ultraviolet radiation field relative to the background Habing value, as defined by [Tielens and Hollenbach \(1985\)](#) and [Bertoldi and Draine \(1996\)](#).

```
Emiss Measure   n(e)n(p) dl      2.205E+25  n(e)n(He+)dl      1.962E+24  En(e)n(He++) dl      1.402E+21
```

This gives several line-of-sight emission measures. The definition of the line of sight emission measure of a species X is (AGN3 section 5.4)

$$E(X) = \int n(e) n(X) f(r) dr \quad [cm^{-5}] \quad (1.10)$$

where $f(r)$ is the filling factor. This is given for H^+ , He^+ , and He^{2+} .

```
He/Ha:9.61E-02 = 1.01*true  Lthin:1.81E+01  itr/zn: 9.78  H2 itr/zn: 0.00  File Opacity: F  MassTot 1.12e32 (gm)
```

This line includes some quantities deduced from the predicted emission-line spectrum. The first (“He/Ha”) number is the apparent helium abundance He/H, measured from the emission-line intensities using techniques described in AGN3 (Chapter 5);

$$\left(\frac{He}{H}\right)_{apparent} = \frac{0.739 \times I(5876) + 0.078 \times I(4686)}{I(H\beta)}. \quad (1.11)$$

The intensities of all lines are the total predicted intensities and include contributions from collisional excitation and radiative transfer effects. The second number (i.e., “1.07*true”) is the ratio of this deduced abundance to the true abundance. This provides a simple way to check whether ionization correction factors, or other effects, would upset the measurement of the helium abundance of the model nebula. This is followed by the longest wavelength in centimeters “Lthin”

at which the nebula is optically thin. Generally the largest FIR opacity source is bremsstrahlung and the number will be 10^{30} if the nebula is optically thin across the full continuum. The number “itr/zn” is the average number of iterations needed to converge each zone while “H2 itr/zn” is the number of iterations per zone required to converge the large H2 model if it is included. “MassTot” gives the total mass of the computed structure in grams if the inner radius was specified. If the inner radius was not specified, and the cloud is plane parallel, then the mass per unit area [gm cm^{-2}] is reported.

```
Temps (21 cm)  T(21cm/Ly a)  8.40E+02  T(<nH/Tkin>)  1.04E+03  T(<nH/Tspin>)  1.29E+03  TB21cm  5.32E+02
N(H0/Tspin)    5.22E+18  N(OH/Tkin)    2.01E+13
```

This line gives various quantities related to the H I 21 cm line. “T(21cm/Ly a)” gives the temperature deduced from the ratio of the 21 cm to $L\alpha$ line optical depths (AGN3 Section 5.5). The opacity within the 21 cm line is proportional to $n(\text{H}^0) \chi/kT$ where χ is the excitation energy of the line. “T(<nH/Tkin>)” gives the harmonic mean temperature

$$\langle T \rangle = \frac{\int T n(\text{H}^0) \chi/kT dr}{\int n(\text{H}^0) \chi/kT dr} \quad (1.12)$$

where T is the electron or gas kinetic temperature. “T(nH/Tspin)” is the temperature derived from the n/T_{spin} ratio using the 21 cm spin temperature. T_{spin} is calculated from the ratio of populations of the ground fine structure levels, which is computed including the effects of $L\alpha$ scattering. The spin and kinetic temperatures are often assumed to be equal although they are not in practice. The number “TB21cm” is an estimate of the brightness temperature of the 21 cm line as viewed from the illuminated face of the cloud. It is the spin temperature at a depth where the 21 cm line becomes optically thick at line center.

On the next line the next two numbers are the H^0 and OH column densities divided by the 21 cm spin temperature in the case of H^0 and by the kinetic temperature in the case of OH. These ratios are proportional to the optical depth of a line at radio frequencies.

```
<a>:0.00E+00  erdeFe0.0E+00  Tcompt1.90E+06  Tthr1.19E+13  <Tden>: 2.38E+01  <dens>:2.00E-17  <Mol>:2.31E+00
```

The mean radiative acceleration “<a>” [cm s^{-2}] is printed if the geometry is a wind model and zero otherwise. This is followed by some time scales. “erdeFe” is the time scale, in seconds, to photoerode Fe (Boyd and Ferland, 1987). This is 0s if the γ -ray flux is zero. The next gives the Compton equilibrium timescale “Tcompt” and the thermal cooling timescale “Tthr” [s]. The density (gm cm^{-3}) weighted mean temperature “<Tden>”, radius-weighted mean density “<dens>” (gm cm^{-3}), and mean molecular weight “<Mol>”, follow.

```
Mean Jeans  l(cm)4.19E+16  M(sun)4.36E-01  smallest:  len(cm):3.53E+16  M(sun):2.61E-01  Alf(ox-tran):  0.0000
```

This gives the mean Jeans length “l(cm)” (cm) and Jeans mass “M(sun)” (in solar units). This is followed by the smallest Jeans length “smallest len(cm)” and the smallest Jeans mass “M(sun)” which occurred in the calculation. The last quantity “Alf(ox-tran)” is the spectral index α_{ox} , defined as in the header, but for the transmitted continuum (attenuated incident continuum plus emitted continuum produced by the cloud).

```
Rion:1.001E+17  Dist:6.17E+21  Diam:6.689E+00
```

This gives the radius of the hydrogen ionization front (in cm), or the outer radius in case the hydrogen ionization front is never reached. This is followed by the distance (in cm), or zero in case the **distance** command was not used. Finally the angular diameter of the ionized region is given (in arcsec), or zero if the distance was not set. The angular diameter is defined as $2 * R_{ion} / Dist$.

```
Hatom level 26 NHtopoff: 22 HatomType: add HInducImp F He tot level: 63 He2 level: 26 ExecTime 2233.72
```

This line gives the number of levels of the model hydrogen atom, the “topoff” level, above which the remainder of the recombination coefficient is added, the type of top off used for this calculation, and the number of levels used for the atomic helium. The last number on the line is the execution wall-clock time in seconds.

```
ConvrgError(%) <eden> 0.075 MaxEden 0.543 <H-C> 0.20 Max(H-C) 0.50 <Press> 0.042 MaxPres 2.535
Continuity(%) chng Te 3.9 elec den 5.8 n(H2) 12.8 n(CO) 8.5
```

The first line gives some estimates of the errors that occurred in several quantities that the code converges. A pair of numbers gives the mean and largest percentage errors for the electron density, the heating-cooling balance, and the pressure. The second line gives the percentage changes that occurred from one zone to the next for the temperature, the electron density, and the H₂ and CO densities.

1.10.5 Average temperatures and densities

	Averaged Quantities										
	Te	Te (Ne)	Te (NeNp)	Te (NeHe+)	Te (NeHe2+)	Te (NeO+)	Te (NeO2+)	Te (H2)	N (H)	Ne (O2+)	Ne (Np)
Radius:	6.86e+02	9.19e+03	9.27e+03	9.18e+03	9.09e+03	9.65e+03	8.86e+03	2.28e+01	8.30e+06	1.43e+04	1.50e+04

This begins with several temperature and density averages, over either radius or volume. The volume averages are only printed if the **sphere** command is entered. The quantity which is printed is indicated at the top of each column. The quantity being averaged is the first part of the label, and the weighting used is indicated by the quantity in parenthesis. For instance “Te(NeO2+)” is the electron temperature averaged with respect to the product of the electron and O²⁺ densities.

```
Peimbert T(OIIIr) 9.08E+03 T(Bac) 0.00E+00 T(Hth) 0.00E+00 t2(Hstrc) 6.01e-03 T(O3-BAC) 0.00E+00 t2(O3-BC) 0.00e+00 t2(O3str) 1.81e-03
Be careful: grains exist. This spectrum was not corrected for reddening before analysis.
```

This series of quantities deal with temperature fluctuations (t^2 , [Peimbert, 1967](#); AGN3 section 5.11). The code analyzes the predicted emission line and continuum spectrum using the same steps that Manuel outlined in this paper. The code does not attempt to correct the predicted emission-line intensities for collisional suppression or reddening, so this line is only printed if the density is below the density set with the **set tsqden** command—the default is 10^7 cm^{-3} . This code does not attempt to deredden the spectrum: a caution is printed if grains are present.

The nature of temperature fluctuations is, in my option, the biggest open question in nebular astrophysics. Theory (CLOUDY too) predicts that they should be very small because of the steep dependence of the cooling function on the temperature, while some observations indicate a very large value of t^2 (see [Liu et al., 1995](#), [Kingdon and Ferland, 1995](#), and [Ferland, 2003](#)). If something is missing from our current understanding of the energy source of photoionized nebulae then the entire nebular abundance scale (for both the Milky Way and the extragalactic nebulae) is in error by as much as 0.5 dex.

Two fundamentally different t^2 s enter here—the “structural” t^2 and the “observational” t^2 . The structural value comes from the computed ionization and thermal structure of the nebula while the

observational value comes from an analysis of the predicted emission-line spectrum following the methods outlined in Peimbert’s 1967 paper.

The structural t^2 for the H^+ ion is defined as

$$t^2(H^+) = \left\langle \left[\frac{T(r) - \langle T \rangle}{\langle T \rangle} \right]^2 \right\rangle = \frac{\int [T(r) - \langle T \rangle]^2 n_e n(H^+) f(r) dV}{\langle T \rangle^2 \int n_e n(H^+) f(r) dV} \quad (1.13)$$

where $\langle T \rangle$ is the density-volume weighted mean temperature

$$\langle T \rangle = \frac{\int T(r) n_e n(H^+) f(r) dV}{\int n_e n(H^+) f(r) dV}. \quad (1.14)$$

This quantity is given in the averaged quantities block as the column “Te(NeNp).”

The observational t^2 —related quantities are the following: “T(OIIIr)” is the electron temperature indicated by the predicted [OIII] 5007/4363 ratio in the low-density limit. This number is meaningless for densities near or above the critical density of the [O III] lines. “T(Bac)” is the hydrogen temperature resulting from the predicted Balmer jump and $H\beta$. “T(Hth)” is the same but for optically thin Balmer continuum and case B $H\beta$ emission. “t2(Hstrc)” is the structural $H\text{ II } t^2$. The entries “T(O3-BAC)” and t2(O3-BC)” are the mean temperature and t^2 resulting from the standard analysis of the [O III] and H I spectra (Peimbert, 1967). Finally “t2(O3str)” is the structural t^2 over the $O2^+$ zone. Only the structural t^2 s are meaningful for high densities. This section was developed in association with Jim Kingdon, and Kingdon and Ferland (1995) provide more details.

The next lines give some information concerning grains if these were included in the calculation. These lines give the mean temperature, drift velocity, and potential, for all of the grain populations included in the calculation. An asterisk will appear to the right of the name of any species with quantum heating included. In this case the mean temperature is weighted by T^4 .

The last line gives some information related to the grain abundance and optical properties. The first number is the dust to gas ratio by mass. The next two are the total visual extinction per unit hydrogen column density for a point and extended source. These are different because of the different effects of forward scattering (AGN3 section 7.6). Next comes the ratio of total to selective extinction. The line ends with A_V for both an extended and point source.

1.10.7 Optical depths

```

Contin Optical Depths: COMP: 1.07e-03      H-: 1.90e-04      R(1300): 4.53e-02      H2+: 1.12e-06      Bra:1.55E+02

```

The first two lines give the continuum optical depths at various energies. These are the total optical depths, including the correction for stimulated emission, and will be negative if maser action occurs. All opacity sources are included. The labels, and their interpretation, are as follows. COMP is the Thomson scattering optical depth. “H-” is the optical depth at the wavelength where the negative hydrogen ion has its greatest maximum cross section. “R(1300)” is the optical depth due to Rayleigh scattering by H⁰ at 1300Å. “H2⁺” is the optical depth at the dissociation threshold of the molecular hydrogen ion. “Bra” is the optical depth at the wavelength of the Brackett α transition (5-4).

The next line gives total continuous optical depths at the energies of various hydrogen and helium ionization edges and mean line optical depths³. These are evaluated at the energies of the Paschen α , Balmer α and β , and L α lines, and the ionization edges of hydrogen, atomic helium, and the helium ion.

The third line gives optical depths of some He I lines. These are computed with a full model of the He⁰ atom (Porter et al., 2005).

```

This lists the column densities (cm^{-2}) of some atoms, ions, and molecules. The first number “Htot” is the total column density of hydrogen in all forms (including atoms, ions, and molecules). The following two numbers are the column densities in H^+ and H^0 . The last four numbers are column densities in four ions and molecules (H^- , H_{2g} , H_2^* , H_2^+ , H_3^+ , and HeH^+). The remaining lines give column densities in various molecules. Molecules with names ending in “grn” are solids that have condensed onto grain surfaces.

The next block gives column densities in atoms and ions of the heavy elements. For hydrogen the last number is the H_2 column density. Column densities within certain excited states of the heavy elements, listed in Table 8.1 on page 78, are also printed. The label gives the element, ionization stage, and level within the ground term. These upper levels are photoexcited by the so-called “level 2 lines”. Their pumping will not be included and excited state column densities will not be predicted if the level 2 lines are disabled with the **no level 2 lines** command.

1.10.9 Mean ionization and temperature

```

The next blocks of output give the log of the mean ionization, averaged over volume, area (if the model is spherical), and over radius. The volume-averaged ionization fraction for ion i of element a is given by

$$\left\langle \frac{n_a^i}{n_a} \right\rangle_{vol} = \frac{\int n_a^i f(r) r^2 dr}{\int n_a f(r) r^2 dr}. \quad (1.15)$$

the area average by

$$\left\langle \frac{n_a^i}{n_a} \right\rangle_{area} = \frac{\int n_a^i f(r) r dr}{\int n_a f(r) r dr}. \quad (1.16)$$

and the radius average by

$$\left\langle \frac{n_a^i}{n_a} \right\rangle_{rad} = \frac{\int n_a^i f(r) dr}{\int n_a f(r) dr}. \quad (1.17)$$

Where n_a is the total gas-phase density and n_a^i is the density in ionization stage i . Similar blocks of information will give the mean ionization weighted by electron density and volume, area, or radius.

Iron	1.803	3.140	3.986	3.952	3.953	3.947	3.956	3.972	3.972	3.972		

The next blocks give the mean temperature weighted by volume, area, and radius. These are followed by the mean temperature weighted by volume, area, or radius and electron density. In all cases the volume and area averages will only be shown in spherical models.

1.10.10 Convergence statistics

```
-----Convergence statistics-----  
1.24 mean iterations/state convergence  
2.67 mean cx acceleration loops/iteration  
1.02 mean iso convergence loops/ion solve  
1 mean steps/chemistry solve  
2 mean step length searches/chemistry step  
-----
```

1.10.11 Final report

```
Cloudy ends: 196 zones, 1 iteration, 1 caution. ExecTime(s) 86.97  
[Stop in maincl, Cloudy exited OK]
```

The code ends by listing the number of zones and iterations that were performed and the number of warnings and cautions that occurred. Next comes the elapsed wall-clock time [s]. The last line will say “Cloudy exited OK” if the calculation is successful.

Chapter 2

OBSERVED QUANTITIES

2.1 Overview

This section describes how to convert the quantities actually used or predicted by CLOUDY into commonly observed ones.

2.2 Intensities of various continua

2.2.1 Incident radiation field

The incident radiation field is the light striking the cloud. The main printout gives the intensity of the incident radiation field with the label “Inci”. The total continuum [units erg s^{-1} or $\text{erg cm}^{-2} \text{s}^{-1}$] integrated over all energies is given with this label and a wavelength of 0. The incident radiation field is also evaluated at two wavelengths, 4860 Å and 1215 Å, as λF_λ or νF_ν , [units erg s^{-1} or $\text{erg cm}^{-2} \text{s}^{-1}$].

The **save continuum** command will produce a file that contains the entire incident radiation field.

These entries will not be included if the **aperture** command is in effect.

2.2.2 The radiation field at specific wavelengths

The intensity of the diffuse radiation field that is emitted or reflected by the cloud is normally included in the main output in the emission-line printout at a series of energies. These have units λF_λ or νF_ν . See the discussion of the **set nFnu** command in Part 1 for further details. You can easily add more continuum points using the **set nFnu add** command, also described in Part 1.

These entries will not be included if the **aperture** command is in effect.

2.2.3 The radiation field integrated over a range of wavelengths

The emitted radiation field integrated over a series of wavelength bands is included in the main printout. The file `continuum_bands.ini` in the data directory specifies a series of wavelength bands. Table 9.1 on page 98 lists the default bands. The label and wavelength that are printed in

the emission-line output are given in the first two columns of that table. The code will integrate over these bands to find the total radiated energy and report this in the main printout. This is a simple summation with no correction for a filter transmission function. The `continuum_bands.ini` file can be edited to change the number of bands or their detailed properties.

This gives the *total* emission that occurs over the band and includes the incident radiation field and both line and continuum diffuse emission. Under many circumstances the radiation field within a band may be dominated by the incident field. The code can also report the emissivity in any of the emission quantities given in the main printout. For these continuum bands the emissivity will only be the diffuse emission from the cloud and will not include the incident field.

These entries will not be included if the **aperture** command is in effect.

2.3 Emission-Line Equivalent Widths

The equivalent width of an emission or absorption line is the number of Angstroms of the continuum that is equivalent to the energy in the line. It is defined as

$$W_\lambda = \int \frac{F_\lambda^c - F_\lambda^t}{F_\lambda^c} d\lambda \approx -\lambda \frac{F_{line}}{\lambda F_\lambda^c} \quad [\text{units of } \lambda] \quad (2.1)$$

where the fluxes are in the incident continuum (F_λ^c), the total transmitted spectrum (F_λ^t), and the line (F_{line}). By this convention the equivalent width of an emission line is negative.

The code's output can be used to predict a line's equivalent width. The previous section describes several of the radiation fields that are predicted. The code prints the intensity or luminosity of all lines and continua and the intensity of each relative to a normalization line.

The ratio of a line to continuum intensity or luminosity will be the dimensionless ratio $F_{line}/\lambda F_\lambda^c$, part of the last term in equation 2.1. The line equivalent width is this ratio multiplied by the wavelength where the continuum is evaluated. The code reports the incident continuum at several wavelengths with labels "Inci". For instance, you could trick the code into printing the relative intensities of the lines as an equivalent width relative to the continuum flux at 1215 Å by including the commands

```
normalize to "Inci" 1215 scale factor = 1215
```

This has two effects. It gives the intensities relative to the incident continuum at 1215 Å and multiplies this by the continuum wavelength in Angstroms, producing the rightmost ratio in equation 1.

Using this trick, all lines will be given as the equivalent width relative to the continuum at the specified wavelength. It is more common to report equivalent widths relative to the continuum near the line itself. You can do this by scaling the incident SED at the wavelength of the **set nFnu** command by the wavelength you want. You can get this information by using the **save continuum** command to obtain the incident radiation field.

These tricks will allow you to get the equivalent width relative to the incident continuum. You can use other options on the **set nFnu** command to choose which spectral components contribute to the underlying continuum.

A covering factor will complicate this slightly. (Covering factors are defined in the section *Definitions* in Part I of this document and in Section 5.9 of AGN3.) In the luminosity case partial coverage of the source is taken into account with the **covering factor** command and the luminosities are correct for this coverage. The ratio of line to continuum given in equation 2.1 will represent what is observed. In the intensity case the line intensity is given per unit area of cloud no matter what covering factor is specified. In this second case the ratio in equation 2.1 must be scaled by the covering factor.

2.4 Emission-Line Asymmetries

The inward fraction of the total emission of each line is always predicted by the code. It is not reported by default. Many lines are significantly inwardly beamed and this can lead to emission-line asymmetries if the envelope is expanding. The inward part of the lines will be printed if the **print line inward** command is entered. Note that the effects of this line beaming are very geometry dependent.

2.5 Surface Brightness

CLOUDY will normally predict a line's intensity as $4\pi J$, the intensity radiated into 4π sr by a unit area of cloud, with units $\text{erg s}^{-1} \text{cm}^{-2}$. Observations of resolved sources often measure the surface brightness, with units $\text{erg s}^{-1} \text{cm}^{-2} \text{arcsec}^{-2}$ or $\text{s}^{-1} \text{cm}^{-2} \text{sr}^{-1}$. Be careful! Some workers may report surface brightness with units $\text{erg s}^{-1} \text{cm}^{-2} \text{arcsec}^{-2} \text{sr}^{-1}$. Remove the sr^{-1} before continuing by multiplying by 4π .

To obtain the predicted surface brightness we must divide the intensity $4\pi J$ by the number of square seconds of arc in 4π sr or the number of sr in 4π sr. One radian is $360/2\pi = 57.29578$ degrees, so 1 sr is $(180/\pi)^2 = 3282.806 \text{ degree}^2$. There are $(60 \times 60)^2$ square seconds in a square degree, so there are 5.3464×10^{11} square arc seconds in 4π sr. The surface brightness (per square second of arc) is the intensity $4\pi J$ multiplied by the inverse of this, or $1.8704 \times 10^{-12} \text{ arcsec}^{-2}$. The surface brightness (per sr) is the intensity $4\pi J$ divided by 4π .

Note that this is only correct for a line that is emitted isotropically, because the code predicts $4\pi J$ while an observer measures I along a particular direction. (The code does predict the fraction of a line that is emitted from the illuminated face of the cloud.) This discussion is only formally correct if $I = J$.

There is a **print line surface brightness** command, described in Section 16.19.19 *Print line surface brightness [arcsec]* of Hazy 1 which will change the intensity into surface brightness units. By default the final units will then be $\text{erg s}^{-1} \text{cm}^{-2} \text{sr}^{-1}$, but the command has an **arcsec** keyword to specify the surface brightness in $\text{erg s}^{-1} \text{cm}^{-2} \text{arcsec}^{-2}$.

2.6 Flux to luminosity

The luminosity is the intensity of a line multiplied by the total area of the shell. For full coverage this is $4\pi r^2$ where r is the radius of the shell. If the shell only partially covers the continuum source then this should be multiplied by the covering factor.

2.7 Flux at the Earth

If the distance to the object is specified with the **distance** command, and the luminosity case is predicted then the flux observed at the Earth will be predicted if the **print flux at Earth** command also appears.

2.8 Relative hydrogen line intensities

Hydrogen line intensities can be predicted with great precision when Case B applies. [Ferguson and Ferland \(1997\)](#) describe CLOUDY’s original hydrogen atom and [Ferland et al. \(2009\)](#) describe its current implementation. It gives good results for all reported lines. The number of reported lines can be increased to go higher in the H I model atom by using the **atom H-like levels** command. This gives better results at the expense of more compute time.

The accuracy of CLOUDY’s H I line emissivities is limited by the size of the model hydrogen atom that can be computed on the fly. The definitive calculation for hydrogen recombination is that of [Hummer and Storey \(1987\)](#) and [Storey and Hummer \(1995\)](#), who used a 1000 level atom with all *l*-levels explicitly considered (that works out to something like a million levels!). The code interpolates on their tables and includes their Case A and Case B predictions within the main printout. The test cases `limit_case*.in` in the test suite compare the code’s predictions with their Case B values.

The [Hummer and Storey \(1987\)](#) calculation is for Case B conditions, which assume that many processes are unimportant (see AGN3). Neglected processes include collisional excitation from the ground or first excited states, induced processes where the incident continuum causes the atom to fluoresce, and line transfer in all non-Lyman lines. Case B is often an excellent assumption for galactic nebulae such as planetary nebulae or H II regions. Case B is not valid for gas densities greater than 10^6 cm^{-3} or when X-rays are present. When any of these processes are important the predictions of CLOUDY’s model atom are more realistic than Case B predictions.

2.9 Helium line intensities

The code includes a model of the He^0 atom that is applied all along the helium iso-electronic sequence. The model can have an arbitrarily large number of levels ([Bauman et al., 2005](#); [Porter et al., 2005](#); [Porter and Ferland, 2007](#)). The predictions become more exact as the number of levels is increased.

2.10 Line intensities in a dusty cloud

Two sets of line intensities are printed in the main output. The first block of lines, with the title “Intrinsic Intensities”, includes all the physics of line formation, including destruction by local background opacities such as grains or photoelectric absorption, but does not include the effects of absorption and scattering of the line from regions away from that were the line forms. This would be the spectrum you would observe after correction for reddening or line of sight extinction.

The second block of emission-line intensities, with the title “Emergent Intensities”, includes the effects of absorption and scattering from regions outside those where the lines form. The distinction is important for optical emission from any geometry that has a large dust extinction A_V , for instance, an H^+ layer on the surface of a molecular cloud.

There are two simple limits for dust extinction. If the simulation only includes the ionized region of a photoionized cloud then dust extinction of optical or IR lines will usually be very small. This is because the *total* optical depth across an H^+ layer is usually $\tau \leq 1$ at 912 Å (Baldwin et al. 1991, Bottorff et al. 1998, AGN3 Chapter 2). The dominant opacity is usually the Lyman continuum of hydrogen so the total dust optical depth is $\tau_{\text{dust}} \ll 1$. Grain extinction is much smaller in the visual than in the FUV around 912 Å, so the visual extinction will also be small. Extinction is even smaller in the IR due to the much smaller grain opacity there. If the optical emission-line spectrum is reddened it may be caused by layers of dust that reside in neutral gas associated with the source, but far more likely the dust is not associated at all with the object you are modeling and resides in the ISM between the source and the observer.

A second geometry is appropriate for star-forming H II regions like the Orion Nebula. This is a blister H II region on the surface of the Orion Molecular Cloud 1 (Zuckerman 1973; Balick et al. 1974; Baldwin et al. 1991; Ferland 2001b). An idealized geometry is shown in Figure 2.1. Two sets of emission lines are observed, see figure 2 of Castaneda (1988), one radiated directly towards the observer and one reflected off of the background molecular cloud (O’deh et al., 1992). On second and later iterations the code computes the fraction of the line emission that is directed towards the illuminated and shielded faces of the ionized layer. The outward line emission is emitted towards the molecular cloud that will have a large optical depth due to grains. The albedo of the gas-grain mixture is computed and the fraction reflected is passed back towards the illuminated face. The total intensities are roughly half what would be expected were the cloud emitting from both sides since much of the light directed into the molecular cloud is absorbed. Something like 10% of the light striking the molecular cloud will be reflected back to the observer, and so slightly more than 50% of isotropically emitted lines will emerge from the illuminated face. The code uses the albedo of the gas at the wavelength of the line to predict this reflected portion and the full optical depths computed on previous iterations.

Although this option was developed with optical emission from the geometry shown in Figure 2.1 in mind, the treatment is actually quite general. All scattering and absorption opacities are considered, so photoelectric absorption and electron scattering are also included, along with all other opacity sources considered by the code. A closed geometry, described in Hazy 1 Section 2.3.4, *Open vs. closed geometry* can also be computed, in which case all emission will filter out through the outer material, including the PDR and molecular cloud surrounding an H II region. The reflected spectrum is not computed for a closed geometry.

The treatment of the emergent spectrum was heavily modified in C17 to take advantage of the current status of the code. When the reflected component of the spectrum was identified by O’deh et al. (1992) it was not possible to extend a CLOUDY calculation into the PDR and molecular cloud to recover this reflected component. PDR physics was identified as a high priority, leading to the Ph.D Theses of Nick Abel (Abel et al., 2005) and Gargi Shaw (Shaw et al., 2005) more than a decade later.

The emergent spectrum was introduced soon after the O’Deh discovery of the reflected spectrum. The implementation was guided by two considerations. First, all star-forming H II regions lie on the surface of a far larger molecular cloud with large A_V . This is a corollary to the

Figure 2.1: The geometry assumed in an open dusty geometry. The panel on the left is part of the HST image of M16, an H^+ layer on the surface of a molecular cloud viewed nearly edge-on. The idealized geometry is shown on the right. The lightly shaded area is the H^+ region, while the darker region to its right is the optically thick molecular cloud. Light produced by an atom in the H^+ region can directly escape from the illuminated face of the cloud. If the atom emits isotropically then roughly half the emission will escape this way. The remaining fraction of the light is emitted towards the molecular cloud where a small part, determined by the albedo, can be reflected back towards the illuminated face.

fact that massive O stars do not live long enough to stray far from their birthplace. Second, CLOUDY could not explicitly compute conditions in the molecular cloud to capture this reflection component.

In versions of CLOUDY between the mid-1990s and C13 the emergent spectrum assumed that the dust optical depth in the outward direction was infinite, a good approximation for a giant molecular cloud. The physics shown in Figure 2.1 could then be captured. This was documented in Hazy1 & Hazy2. The behavior was changed in C17 to only include absorption and scattering by the computed geometry. The scattering component will only be computed if the calculation extends into the molecular cloud. It is not necessary to compute the full molecular cloud. The calculation has to extend to a large optical depth at visual wavelengths. This might be done with, for example, by combining the commands **stop Av 3** and **stop temperature off** to extend the calculation well into the PDR.

These predictions are only reliable once the radiative transfer and line optical depths are well converged. Consider using the **iterate to convergence** command described in Hazy 1 Section 10.7, *Iterate [2 times, to convergence]*.

2.11 Continuum pumping contribution to line intensities

Continuum pumping or fluorescence is included for all lines. The contribution is only explicitly reported if the **print line pump** command is entered. Whether or not this contribution actually adds to the observed line emission depends on the geometry. Continuum pumping increases the line emission if no related continuum absorption occurs. This will be the case if the continuum source is either not observed or not covered by absorbing gas. If absorbing gas covers an observed continuum source then the situation is like the P Cygni problem, and pumping may not increase the net intensity of the line at all (the absorption component will have the same equivalent width as the associated emission). The printed line intensity includes this contribution unless the **no induced processes** command is entered. (The **no induced processes** command has many other effects and so should only be used as a test.)

The output produced by the **save continuum** commands does not include the pumped part of the line contribution. This is correct if the continuum source is included in the beam, but is not if only the gas is observed.

2.12 Column densities

The column densities of all constituents are printed at the end of the calculation. Column densities within many excited states are also printed. The excited states are identified with a '*'. The table that accompanies the description of the **cdColm** command (see Table 8.1 on page 78 above) identifies the various labels.

2.13 A synthetic spectrum

A table of emission-line intensities is part of the normal output. Sometimes a synthetic spectrum, rather than a table, is desired. Very coarse spectra can be generated with the **save continuum** or

save spectrum commands, but a detailed synthetic spectrum is not the main purpose of this output.

It is best to save the emission-line spectrum and then post-process this data using your own software. Then blends of lines can be synthesized at any spectral resolution desired. The spectrum can be save two ways. The main block of emission-line intensities in the final printout can be printed as a single column, which can be sorted by intensity or wavelength (by using options on the **print lines** command in Section 1 of this document). The **save lines, array** command can report the emission lines. Write a small program or script to read these tables and create a final synthesized spectrum.

2.14 Line profiles

The observed line profile can be predicted by integrating the emissivity of the line over the computed structure while taking the local velocity structure into account. The emissivity is obtained with the **save lines emissivity** command, described in Part 1 of this document. This gives the net emission, with units $\text{erg cm}^{-3} \text{ s}^{-1}$, emitted by a unit volume of gas and emergent from the cloud surface. The total emission is the integral of the emissivity. An integral over radius will give the line intensity $4\pi J$ while an integral over volume will give the luminosity.

The observed profile will depend on the velocity field at each point in the integration. For static models this will be the Voigt function at the local temperature and microturbulence. For a dynamical model it will include bulk motion of the gas.

Chapter 3

LIMITS, ASSUMPTIONS, AND RELIABILITY

3.1 Overview

This section outlines some of the assumptions and limits that define the range of validity of CLOUDY. The code is designed to be autonomous and self-aware, and to check that these limits are not exceeded during a calculation. This self-checking is a central feature of the code since it is designed to be used to compute large grids with thousands of models, where the examination of individual results would not be possible. CLOUDY should print a warning after the last zone results if any aspects of the calculation are in doubt.

3.2 Time steady

CLOUDY does not assume that the gas is in equilibrium. In most cases it does, however, assume that atomic processes occur on timescales that are much faster than other changes in the system, so that atomic rates have had time to become time-steady. It is possible to follow time-dependent conditions or an advective flow.

In practice most calculations assume that the cloud is old enough for atomic processes to have become time steady. The **age** command (described in Part I of this document) should be used to specify the age of the cloud. The code will then confirm that the time-steady assumption is valid by comparing the system's age with a host of rates and timescales, and will generate a warning if the environment is not time-steady.

Various time scales characterize the approach to equilibrium of an ionized gas (see [Spitzer, 1962](#), and [Ferland, 1979](#) for a specific application). Generally, for an ionized gas with nebular temperatures ($T \sim 10^4$ K), the longest is the H^+ recombination time scale,

$$T_{rec} = \frac{1}{\alpha_A(T_e) n_e} = 7.6 t_4^{0.8} n_4^{-1} \text{ years} = 0.66 t_4^{0.8} n_9^{-1} \text{ hours} \quad (3.1)$$

where t_4 is the temperature in units of 10^4 K, n_9 is the electron density in units of 10^9 cm^{-3} , and case A recombination is assumed (AGN3).

The time scales are far more ponderous in molecular regions. Generally among the longer of the time scales is the time to form H^- , an important pacesetter for H_2 formation in grain-free environments. This time scale is roughly given by

$$T_{\text{molecule}} = \frac{1}{\alpha_{\text{rad}}(T_e) n_e} = 0.3 t_3^{-0.8} n_9^{-1} \text{ years} \quad (3.2)$$

where t_3 is the temperature in units of 10^3 K .

If the age of the cloud is not long enough for atomic processes to become time steady then a time-dependent calculation should be done. If the gas flow is fast enough for advection to add significant terms to the statistical equilibrium equations then a wind calculation should be performed. Commands for these simulations are described in Chapter 14, *DYNAMICAL & TIME-DEPENDENT CALCULATIONS*, in Hazy 1.

3.3 Atomic and molecular database

This section outlines some of the atomic and molecular physics issues that affect the reliability of numerical simulations of nebulae. These uncertainties were extensively discussed in the Lexington Plasma 2000 meeting (ASP Conf series 247, *Spectroscopic challenges of photoionized plasmas*, Gary Ferland & Daniel Savin, editors) and they underscore the importance of atomic and molecular physics for the interpretation of astrophysical spectroscopy.

3.3.1 Collisional processes

By its nature, the electron temperature of a photoionized gas is low compared with the ionization temperature of the mixture of atoms and ions, as defined by the Saha equation (if the two were comparable, the gas would be collisionally ionized). Because of this, the rate coefficients describing collisional effects, such as the production of cooling emission lines, are often dominated by the cross sections near threshold. This is where laboratory experiments are difficult and *ab initio* quantum theory must often be used. As a result, the collision strengths undergo constant revision, towards better and more reliable values.

To cite one extreme example, the collision strength for transitions within the 3P ground term of Ne^{+4} underwent three revisions between 1984 and 1991, each by a factor of 10, because of theoretical uncertainties in positions of autoionizing states with unknown energies (Lennon and Burke, 1991). The intensities of all emission lines can be affected by major changes in the atomic data for only one line for some conditions. This is because (in this case) the infrared fine structure lines of Ne^{+4} can be important coolants in low-density high-ionization gasses such as planetary nebulae, and changing their cooling rate alters the thermal structure of the entire nebula. Such changes often give even models of time-steady objects such as planetary nebulae certain time-dependent characteristics.

At present, there are fairly reliable calculations of collision strengths and transition probabilities for the majority of the strong optical and ultraviolet lines in moderate ionization nebulae. A series of papers by Oliva and collaborators (see Oliva et al., 1996 and van Hoof et al., 2000) outline observational evidence concerning accuracies in collision strengths of moderate ionization far infrared lines.

Some strong cooling lines of high ionization species do not have accurate collision rates. As an example, few of the “level2” lines included in the code have real collision strengths. Various forms of the “g-bar” approximation are used for those lines that do not have accurate collision rates.

3.3.2 Photoionization cross sections

The photoionization cross-section database has undergone a dramatic improvement with the completion of the Opacity Project ([Seaton, 1987](#)) and its fitting with analytic approximations ([Verner et al., 1996](#)). These are the photoionization cross sections used by CLOUDY and they should be as accurate as 10%. All inner shell multi-electron processes are included ([Kaastra and Mewe, 1993](#)) using distorted wave cross sections (referenced in Verner et al.). This part of the data base is in fairly good shape, although greater accuracy is always desired.

“Fano profiles”, due to autoionization resonances, appear as large changes in photoionization cross section that occur over a narrow range of energy, are averaged over, as described by Verner et al. Their positions are not accurately known, and they could make a difference if sharp spectral features occur in the stellar continuum at the position of a resonance. The photoionization rate could be changed dramatically in this case. Experimental data would be needed to upgrade the photoionization data base to include Fano profiles.

3.3.3 Recombination rate coefficients

Recombination from closed shell species is accurately known ([Verner and Ferland, 1996](#)) since these are dominated by radiative recombination. Reliable dielectronic recombination coefficients do not now exist for most other stages of ionization. Currently there is no theory that can reproduce the best experiments ([Savin et al., 1999](#)). For these, CLOUDY uses the guestimates described in Part I of this document. This is clearly the greatest single gap in the atomic data base today. [Savin \(2000\)](#) shows an example where this uncertainty has a direct impact on cosmological studies.

3.3.4 Charge transfer

The rate coefficients for charge transfer are another uncertainty in the atomic and molecular database. This process is sometimes the dominant neutralization mechanism for singly or doubly ionized heavy elements. At present many charge exchange rate coefficients are the result of Landau-Zenner calculations using semi-empirical potential curves ([Kingdon and Ferland, 1996](#), [Kingdon and Ferland, 1999](#)). These are thought to be no more accurate than a factor of three. Even the best quantal calculations are not thought to have an accuracy much better than 50 percent. Unpublished tests suggest that these uncertainties affect some line intensities at the $\sim 20\%$ level, and a few by more than this.

3.4 Continuous opacity

All significant continuous opacity sources are treated for the energy range considered by the code, 3.040×10^{-9} Ryd to 7.354×10^6 Ryd. These opacity sources include inverse bremsstrahlung,

grains (when present), H^- absorption, electron scattering, the damping wings of strong resonance lines (i.e., Rayleigh scattering), pair production, photoelectric absorption by the ground and excited states of all ions of the lightest 30 elements, and photoabsorption by molecules. This treatment should be adequate as long as the optical depths to electron scattering are not large. CLOUDY is not now designed to simulate Compton-thick regimes. (A warning will be issued after the last zone calculation if the nebula is very optically thick to electron scattering.)

3.5 Temperature range

CLOUDY assumes that the electrons are non-relativistic, which limits it to temperatures below roughly 10^9 K. CLOUDY goes to the Compton temperature of the radiation field to great accuracy in the limit of very high levels of ionization for blackbody radiation fields with temperatures between 2.8 K and 1.001×10^{10} K. There is no formal lower temperature limit to its validity. Note that very cold gas is rarely in steady state, however, because of the very slow collision rates. Similarly, the collision timescales in very hot gas ($T \gg 10^8$ K) are not rapid enough to ensure that the electrons and ions have the same temperature, or that heating - cooling balance has become time steady (Johnson and Quataert, 2007). Electron-ion decoupling is not now included.

The range of validity of the code is approximately from 10 K to 10^9 K. Temperatures outside this range can still be treated, although with greater uncertainty. The code will not permit temperatures below 2.8 K or above 1.001×10^{10} K.

3.6 Density range

There is no formal lower limit to the density that CLOUDY can treat. The set of heavy element fine structure lines, which dominate cooling at low densities, is complete for astrophysically abundant elements, and fine structure line optical depths, continuum pumping, and maser effects are fully treated.

There is no formal high-density limit, although the simulation is less complete at high ($n \cong 10^{10} \text{ cm}^{-3}$) densities. Line radiative transfer processes are fully treated with either escape or Sobolev approximations (see Kalkofen, 1987 and Avrett and Loeser, 1988) and collisional-radiative ionization processes for excited levels of the heavy elements are treated. All species of H-like and He-like isoelectronic sequences are treated as many-level atoms, including all of the physical processes that allow the approach to LTE (see, for example, Mihalas, 1978). Tests with a hydrogen density of 10^{19} cm^{-3} show that the hydrogen and helium atoms and the hydrogen molecules go to LTE at high densities. They go to strict thermodynamic equilibrium when exposed to a true black body. The treatment of Stark broadening for hydrogen lines follows Puetter (1981), so line radiative transfer is treated correctly (in the context of the escape probability formalism) for densities above $\sim 10^{10} \text{ cm}^{-3}$.

The treatment of the other 28 isoelectronic sequences is presently not as complete as the H and He-like sequences. Three-body recombination is included as a general recombination process, so the treatment of these elements is approximately correct at high densities.

CLOUDY has been tested at densities of 10^{-8} cm^{-3} and 10^{19} cm^{-3} on 32-bit machines. The numerical (not physical) limit to the density will actually be set by the limits to the range of the

floating point numbers allowed by the machine in use. The physics incorporated in the code imposes no lower limit to the density. The physical high-density limit is roughly 10^{15} cm^{-3} , and is set by the approximate treatment of three-body recombination - collisional ionization for the heavy elements.

3.7 Radiative transfer

Several tests presented in the test suite show that the continuum transfer methods are in excellent agreement with known exact results.

Line intensities are predicted with stellar atmosphere conditions in mind. Radiative transfer effects, including continuum pumping and possible maser emission, are treated. Nebular approximations, such as the approximation that all atoms are in the ground state, are not made. Collisional effects, including excitation and de-excitation, continuum fluorescence, recombination, etc, are all included as general line excitation mechanisms. The treatment of level populations is designed to go to LTE in the high particle or photon density cases.

The transfer of subordinate lines, those where both upper and lower level of the transition occur in excited state, of the H-like and He-like iso sequences at high ($n \gg 10^{10} \text{ cm}^{-3}$) densities is a concern. Resonance lines should be fine.

3.8 Reliability

Several issues affect the general question of the reliability of the code. The first is the effects of the bugs that surely must exist in a code the size of CLOUDY. I have seldom found bugs in sections of the code older than roughly two to three years. Younger sections of the code sometimes contain bugs that only manifest themselves in exceptional situations. The issue of reliability in the face of complexity will increasingly be the single major problem limiting the development of large-scale numerical simulations (Ferland, 2001a). New methods of writing code will have to be developed if we are to take full advantage of the power of future machines. Machines are getting faster more quickly than people are getting smarter.

The second issue is the validity of the numerical methods used to simulate conditions in the plasma. Fundamental uncertainties arise for cases where the density is high ($n \gg 10^{10} \text{ cm}^{-3}$). The line radiative transfer techniques used by CLOUDY are approximate (see the discussion by Avrett and Loeser, 1988). Unfortunately, no definitive calculation now exists for the complete non-LTE equilibrium and line emission for an intermediate density $\sim 10^{13} \text{ cm}^{-3}$ cloud. For less extreme conditions ($n < 10^{10} \text{ cm}^{-3}$) nebular approximations are valid.

Test cases that are designed to exercise the code in well-posed limits and for certain standard nebulae are in the test suite. The code is well behaved and agrees with predictions of similar codes in these limits. The discussion presented in Ferland (1995) and Péquignot et al. (2001) suggests that 10% accuracy can be reached for the intensities of the stronger lines.

The uncertainties can probably best be judged by looking at both the dispersions among the various photoionization calculations presented in Ferland (1995) and Péquignot et al. (2001), and by the changes in the test suite. Much of the dispersion is due to improvements in the atomic database.

There can be little better way to close a discussion of reliability than to quote the warning included in the description by (Kurucz, 1970, see page xiii) of ATLAS5, a code more than an order of magnitude smaller than CLOUDY:

WARNING

“There is no way to guarantee that ATLAS5 does not contain errors. In fact, it is almost certain that it does, since the code is so long... . We also point out that the computation of a model atmosphere should be considered a physical experiment. The program may not be able to calculate a model for conditions that do not occur in real stars or for conditions that violate the initial assumptions on which the program is based.”

3.9 The future

The eventual goal is for CLOUDY to give reliable results for all extremes of conditions between and including the intergalactic medium and stellar atmospheres. I estimate that the code is now well over halfway complete.

Current work centers on taking advantage of parallel machines. Once finished, we will be able to use this additional computational power to improve the treatment of hydrodynamics, line radiative transfer, and higher-order dimensionality.

Chapter 4

THE CONTINUUM

4.1 Overview

Under most circumstances the radiation field produced by the central object is the only source of heat and ionization. This section describes how this continuum is treated.

4.2 Attenuation of the incident continuum

In an *open geometry* scattering attenuates the incident continuum as

$$I = I_o(1 + 0.5 d\tau_{scat})^{-1}. \quad (4.1)$$

Scattering does not affect the continuum in a *closed geometry*. Absorption attenuates the incident continuum as

$$I = I_o \exp(-d\tau_{abs}). \quad (4.2)$$

for both geometries.

4.3 Recombination equilibrium

4.3.1 On-the-spot approximation

A modified version of the “on-the-spot” (OTS) approximation is used in the treatment of sources of diffuse ionizing radiation when the **diffuse OTS** command is used. Were no other opacity sources present, then, for a closed geometry that is optically thick in the Lyman continuum, all recombinations of hydrogen or helium to the ground state would produce ionizing photons. Other atoms of the recombined species would quickly absorb these. In this case OTS is an excellent approximation ([van Blerkom and Hummer, 1967](#); [Baessgen et al., 1988](#)). However, other opacity sources are present, and these compete in absorbing photons produced by recombinations, making the recombination process more efficient than the OTS approximation would suggest.

The recombination coefficients are modified by the presence of all other opacity sources, such as grains, free-free or H^- absorption, and the heavy element opacities, in the following manner. The net effective recombination rate coefficient ($\text{cm}^3 \text{s}^{-1}$) to level n , $\hat{\alpha}(T_e, n)$, is written in terms

of the spontaneous radiative recombination rate coefficient $\alpha(T_e, n)$ and the opacities (cm^{-1}) κ_n and κ_o for the level n and other opacity sources respectively, as

$$\hat{\alpha}(T_e, n) = \alpha(T_e, n) \left\{ P_c(n) + [1 - P_c(n)] \left(\frac{\kappa_o}{\kappa_o + \kappa_n} \right) \right\}, \quad (4.3)$$

where $P_c(n)$ is the continuum escape probability. In general, $P_c(n)$ varies between 0 and 0.5 for an optically thick open geometry (see, for example [Davidson, 1977](#)), $P_c \sim 1$ if the gas is optically thin, and $P_c \sim 0$ for ground states if the gas is optically thick and the geometry is closed. All computed opacity sources are included in κ_o .

These recombination continua produce a flux of local on-the-spot photons, ϕ_{OTS} ($\text{cm}^{-2} \text{s}^{-1}$). The OTS photoabsorption rate Γ_{OTS} (s^{-1}), used to determine the ionization or heating rate for the gas or grain constituents, is then $\Gamma_{OTS} = \alpha_\nu \phi_{OTS}$ where α_ν is the absorption cross section at frequency ν . The OTS flux is related to the spontaneous recombination rate coefficient by

$$\phi_{OTS} = \alpha(T_e, n) n_e n_{ion} \left[\frac{1 - P_c(\tau)}{\kappa_o + \kappa_n} \right] \text{cm}^{-2} \text{s}^{-1} \quad (4.4)$$

where n_{ion} is the density of the ion. These are stored in the vectors *otscon* and *otslin*, which map one-to-one onto the vectors *flux* and *anu*.

4.3.2 Outward only approximation

A composite “outward-only” ([Tarter, 1967](#)) – “on-the-spot” approximation is used in the treatment of sources of diffuse ionizing radiation when the **diffuse outward** command is used. This is the default assumption. The escaping radiation is then propagated in the outward direction (all for the spherical case, and half for an open geometry).

4.4 Continuous opacities

The cloud is divided into a large number of concentric shells (zones) and the attenuated and diffuse continua and physical conditions are then determined within each.

The main opacity sources in the ultraviolet continuum are generally photoelectric and free-free (inverse bremsstrahlung) absorption, grain opacity, electron scattering (of both bound and free electrons), and the damping wings of Lyman lines (Rayleigh scattering). The main reemission mechanisms are generally free-free (bremsstrahlung), grain emission, free-bound, and two-photon emission. Grains are not present by default but can be added as an option. Continuous absorption and reemission by all ground states, and many excited states, of all ionization stages of the 30 elements in the calculation are explicitly included. Great care is taken to ensure that each absorption mechanism is balanced by a reemission process, and vice versa, so that energy balance in the strict thermodynamic equilibrium limit can be achieved.

4.4.1 Total opacity arrays

Total absorption opacities (cm^{-1}) are stored in the vector *opac*. Total scattering opacities (cm^{-1}) are stored in *scatop*. The opacities are evaluated in routine *ConvIonizeOpacityDo* and are within the *opac* structure (defined in *opacity.h*).

4.4.2 Cross-section array

Storage. The cross sections per particle (cm^2) for individual species (atoms, ions, molecules, etc) are stored within the array *OpacStack*, a stack array with a single dimension. These cross sections are evaluated when the code is initialized in routine *OpacityCreateAll*.

Array indices. Each species has an associated array index that defines the offset between the origin of *OpacStack*, the frequency array *anu*, and the opacity at the threshold. If this offset has the name *ioff*, for instance, then the cross section at threshold will be given by array element *OpacStack[ioff]*. If *ip* is the index to the threshold energy within *anu*, then the array index to the cross section at energy *i* will be $i - ip + ioff$.

Individual cross-sections. The function *csphot* returns the cross section at a specific frequency for any species. It has three arguments, 1) the pointer to the frequency in *anu* where the cross section is to be evaluated, 2) the pointer to the threshold for the species, and 3) the *ioff* offset described above. All are integer variables.

4.4.3 Photoionization rates

Photoionization rates (units s^{-1}) can be computed by several functions. Which is used at a particular time is determined by circumstances.

GammaK This computes the photoionization rate with allowance for an arbitrary fluorescence yield. This routine is a major pacesetter for the code since it is used to evaluate the continuum rates in the majority of the cases. The photoionization rate is given by

$$\Gamma_n = 4\pi \int_{\nu_o}^{\infty} \frac{J_\nu}{h\nu} \alpha_\nu d\nu \quad [\text{s}^{-1}]. \quad (4.5)$$

where α_ν is the photoionization cross section [cm^2]. The routine has three integer arguments, the *anu* pointers to the lower and upper energies and the offset to the opacity array *ioff* (described above).

GammaPrt This is a special version of *GammaK* that writes the step by step results of the integration on any open file. The output lists the product of the photon flux and the cross section, the photon flux, and the opacity.

GammaBn This is a special version of *GammaK* that is used when the correction for stimulated emission or induced recombination is important. The photoionization rate is given by

$$\Gamma_n = 4\pi \int_{\nu_o}^{\infty} \frac{J_\nu}{h\nu} \alpha_\nu d\nu \quad [\text{s}^{-1}] \quad (4.6)$$

and the rate for induced recombination and its associated cooling is computed as

$$\alpha(\text{ind}) = P_n^* 4\pi \int_{\nu_o}^{\infty} \frac{J_\nu}{h\nu} \alpha_\nu \exp(-h\nu/kT) d\nu \quad [\text{cm}^3 \text{s}^{-1}]. \quad (4.7)$$

where P^* is the LTE population.

GammaPrtRate will print photo rates for all shells of an ion and element. It is called with three arguments, a file handle, followed by the ionization stage and element number on the C scale (0 for H or atoms, etc).

4.4.4 Attenuation within the zone

A correction must be made to account for the attenuation of the continuum across the zone (Netzer and Ferland, 1984). Assuming that the continuum varies across the zone as

$$\frac{I(\nu, \delta r)}{I_o(\nu)} = \exp(-\kappa(\nu) f(r) \delta r) \quad (4.8)$$

then the intensity averaged over a zone with thickness δr is

$$\left\langle \frac{I(\nu, \delta r)}{I_o(\nu)} \right\rangle = \frac{1 - \exp(-\kappa(\nu) f(r) \delta r)}{\kappa(\nu) f(r) \delta r} \quad (4.9)$$

where $\kappa(\nu)$ is the absorption opacity and $f(r)$ is the filling factor. The coefficients giving this ratio as a function of energy are stored in the vector *tmn*, and are evaluated in routine *radinc*. The continuum stored in *flux* is multiplied by these factors in the same subroutine.

4.4.5 Rayleigh scattering

Clouds with neutral hydrogen column densities greater than 10^{23} cm^{-2} are optically thick to Rayleigh scattering at wavelengths near $\text{L}\alpha$, and this process is a major scattering opacity source at short wavelengths for grain-free environments.

Rayleigh scattering cross sections given by Gavrilu (1967) are used, joined with expressions for the radiative damping wings of Lyman lines (Mihalas, 1978). For wavelengths longward of 1410 Å a power-law fit to Gavrilu's quantal calculations is used;

$$\sigma_{Ray} = 8.41 \times 10^{-25} \epsilon^4 + 3.37 \times 10^{-24} \epsilon^6 + 4.71 \times 10^{-22} \epsilon^{14} \quad \text{cm}^2 \quad (4.10)$$

where $\epsilon \equiv /cR_\infty$ is the photon energy in Rydbergs. This fit is accurate to typically a percent, with occasional errors as large as 4 percent.

For wavelengths between 1410 Å and the Lyman limit, radiative broadening of the Lyman lines is assumed (Mihalas, 1978);

$$\sigma_{Ray} = \sum_{i=2}^4 \left(\frac{q_e^2 f_{1,i}}{m_e c} \right) \frac{\Gamma/4\pi}{(\nu - \nu_{1,i})^2} \quad \text{cm}^2 \quad (4.11)$$

where Γ is the reciprocal lifetime of the upper level i and the sum is over the first four Lyman lines. This expression gives cross sections in excellent agreement with Gavrilu (1967) for these wavelengths.

4.4.6 Free-free opacity

The main opacity source in the infrared-radio spectral region for many conditions is free-free opacity with a cross section given by

$$\alpha_\nu(ff) = 3.69 \times 10^8 \bar{g}_{III}(\nu, T) f(r) \nu^{-3} T^{-1/2} \{1 - \exp(-h\nu/kT)\} \sum_A \sum_z z^2 n_A^{+z} \quad [\text{cm}^{-2}] \quad (4.12)$$

Figure 4.1: Thermally averaged free-free gaunt factor. The gaunt factor is shown as a function of photon energy and temperature.

(see, for example, [Mihalas, 1978](#)). The sum is over all ions n^{+z} of element A and over all elements. The temperature averaged gaunt factor $\bar{g}_{III}(\nu, T)$ is taken from [Hummer \(1988\)](#) (see also [Karzas and Latter, 1961](#)) and are evaluated in routine *gffsub* that was originally written by D. Hummer.

This routine did not extend to energies that could be treated by asymptotic expansions of the gaunt factor. *gffsub* was modified by J. Ferguson to extend over the full temperature and energy range considered by CLOUDY, and later extensively rewritten by Ryan Porter. Figure 4.1 shows the gaunt factors as functions of photon energy and temperature.

4.4.7 Bound-free opacity

Continuum optical depths for photoabsorption from level l are given by

$$d\tau_l(\nu) = \alpha_\nu(n) n_l [1 - \exp(-h\nu/kT)/b_l] f(r) \delta r \quad (4.13)$$

where b_l is the departure coefficient for level l and α_ν is the absorption cross section [cm^{-2}].

4.4.8 Plasma frequency

The plasma frequency, the energy where the index of refraction of an ionized medium goes to zero, is given by

$$\nu_{pl} = \left(\frac{n_e q_e^2}{\pi m_e} \right)^{1/2} = 8.978 \times 10^3 n_e^{1/2} s^{-1} = 2.729 \times 10^{-12} n_e^{1/2} \text{ Ryd} \quad (4.14)$$

An ionized gas will reflect the incident continuum for energies smaller than this. This shielding becomes important for the energy range considered by CLOUDY for electron densities greater than $\sim 10^7 \text{ cm}^{-3}$. For higher densities this process is treated by setting the intensity of the incident continuum to zero for energies below the plasma frequency, adding this portion of the incident continuum to the reflected continuum, and not allowing emission or absorption for any processes that occur below the plasma frequency.

4.4.9 Pressure lowering of ionization potential

The electric field of nearby charges in the continuum acts to lower the ionization potential. The amount by which it is lowered is determined by the electron density. Ryan Porter extended the code to consider all species treated with the iso-electronic model atoms.

4.5 The frequency mesh

The energy interval $3.040 \times 10^{-9} \text{ Ryd} - 7.354 \times 10^6 \text{ Ryd}$ is divided into a number of sections using the contents of the file `continuum_mesh.ini`. Each of these sections has an associated mesh resolution r , and is filled with a large number of frequency cells with nearly exponentially increasing widths.

4.5.1 Frequency mesh logic

To define the frequency mesh, the code will first set up an array of edge frequencies ν^{edge} that define the lower and upper limit of each frequency cell. Assuming we want to set up the edges in a section starting at energy ν_0 and ending at ν_1 , the first step is to determine how many frequency cells n_{bin} we will generate in that section:

$$n_{\text{bin}} = \left\lceil \frac{\ln(\nu_1/\nu_0)}{r} \right\rceil. \quad (4.15)$$

From this we can calculate the frequency step size ν_s :

$$\nu_s = \exp \left[\frac{\ln(\nu_1/\nu_0)}{n_{\text{bin}}} \right]. \quad (4.16)$$

Finally, the frequency of edge number i is defined simply by:

$$\nu_i^{\text{edge}} = \nu_0 \nu_s^i \quad (4.17)$$

for $i \in [0, n_{\text{bin}}]$. Once the edges are defined, we can simply define the center of each frequency cell as the exact midpoint between the two edges, and the width as the difference between the two edge energies.

4.5.2 Routines defining the frequency mesh

Several routines can be used to obtain properties of the frequency mesh, all returning values in Rydberg. The function *anu(i)* gives the energy of the center of frequency cell number *i*. The functions *anumin(i)* and *anumax(i)* give the lower and upper frequency limit of cell number *i*, respectively. The routine *widflx(i)* gives the width of cell number *i*. There are also routines to obtain simple mathematical functions of the center frequency, such as the square, the cube, the square root, or the logarithm. The data used by these routines are set up in the routine *t_mesh::p_SetupMesh*.

4.5.3 Changing the resolution of the mesh

The file `continuum_mesh.ini` contains ordered pairs of continuum energies and resolving powers (defined as $1/r$) that are read by *t_mesh::p_ReadResolution* to set the frequency mesh. Change the contents of `continuum_mesh.ini` to change the resolution of the continuum mesh. The file explains how to do this.

Alternatively, you can also use the command **set continuum resolution** that will apply a uniform multiplicative factor to the resolution in each section defined in `continuum_mesh.ini`. This command is explained in Section 19.13.9 in Hazy 1.

If the energy resolving power is increased then the code will require more mesh points to cover the full continuum and will run more slowly, but the predicted continuum will have greater detail.

4.6 Continuum generation

The continuum is generated by the function *ffun*. *ffun* has a single argument, the energy in Rydbergs, and it returns the number of photons per unit area, time, and Rydberg, at that energy. *ffun* sums over all the specified continua and applies the appropriate normalization factors. Another function, *ffunI*, evaluates each individual continuum, and is normally called only by *ffun*.

The units, and their conversion to other measures of the continuum, are given below. The photon flux density is:

$$\phi_v(v) = \text{ffun}(v) \quad [\text{photons cm}^{-2} \text{s}^{-1} \text{Ryd}^{-1}]. \quad (4.18)$$

This is stored in the photon array:

$$\text{flux}(v_i) = \phi_v(v) \delta v_i = \text{ffun}(v_i) \times \text{widflx}(v) \quad [\text{photons cm}^{-2} \text{s}^{-1}] \quad (4.19)$$

where *widflx* is an array containing the width of each continuum bin. Finally, the energy flux density is given by

$$f_v(v) = \text{ffun}(v) h \left(\frac{v}{v_{912}} \right) \quad [\text{erg cm}^{-2} \text{s}^{-1} \text{Hz}^{-1}] \quad (4.20)$$

and

$$v f_v(v) = \text{ffun}(v) h \left(\frac{v}{v_{912}} \right) v_{912} h v_{\text{Ryd}} \quad [\text{erg cm}^{-2} \text{s}^{-1}]. \quad (4.21)$$

4.7 Energy units; the Rydberg

Continuum energies are usually given in Rydbergs. The energy of level n of a hydrogenic atom is given by

$$E_n = -\frac{\mathcal{R}_H}{n^2}, n = 1, 2, 3, \dots, \quad [\text{units of } \mathcal{R}_H] \quad (4.22)$$

where the Rydberg energy is given by

$$\mathcal{R} = \frac{\mu q_e^4}{2\hbar^2} = \frac{\mu}{m_e} \mathcal{R}_\infty \quad (4.23)$$

and the reduced mass of the orbiting electron μ is related to the electron and nuclear mass m_e and m_{nuc} by

$$\mu = \frac{m_e m_{nuc}}{m_e + m_{nuc}} = \frac{m_e}{1 + m_e/m_{nuc}} \quad [\text{g}], \quad (4.24)$$

(Friedrich, 1998). Note that as $m_{nuc} \rightarrow \infty$, $\mu \rightarrow m_e$. This Rydberg energy \mathcal{R}_H is smaller than the energy for an infinite mass nucleus \mathcal{R}_∞ by the ratio μ/m_e . Using the 1998 CODATA revision of the fundamental constants (see Cohen and Taylor, 1987; Mohr and Taylor, 2000) the infinite mass Rydberg energy is given by

$$\mathcal{R}_\infty = \frac{m_e q_e^4}{2\hbar^2} = 13.605698 [\text{eV}] \quad (4.25)$$

and

$$\begin{aligned} \mathcal{R}_\infty / (2\pi\hbar c) &= 109737.315686 \text{ cm}^{-1} \\ \mathcal{R}_\infty / (2\pi\hbar) &= 3.28984196038 \times 10^{15} \text{ Hz} \\ (2\pi\hbar c) / \mathcal{R}_\infty &= 91.126732 \text{ nm} \end{aligned} \quad (4.26)$$

The ionization potential of hydrogen \mathcal{R}_H is μ/m_e or ~ 0.99946 times smaller than \mathcal{R}_∞ .¹ We have

$$\begin{aligned} \mathcal{R}_H &= 13.59842 \text{ eV} \\ \mathcal{R}_H &= 2.179872 \times 10^{-11} \text{ erg} \\ (2\pi\hbar) / \mathcal{R}_H &= 91.176430 \text{ nm} \\ \mathcal{R}_H &= 109677.576 \text{ cm}^{-1} \end{aligned} \quad (4.27)$$

The difference between \mathcal{R}_H and \mathcal{R}_∞ is significant since it enters as the third power in the photon phase-space conversion factor $2h\nu^3/c^2$.

The Bohr radius is for an infinite mass nucleus is given by

$$\begin{aligned} a_o &= \hbar^2 / (m_e q_e^2) = 0.5291772083 \times 10^{-8} \text{ [cm]}. \\ a &= a_o / \mu \end{aligned} \quad (4.28)$$

In the “atomic units” system of measuring quantities lengths are given in terms of the Bohr radius and energies in “Hartree” units. One Hartree is twice the Rydberg energy.

¹ \mathcal{R}_H was the Rydberg unit used by CLOUDY before 1988.

Chapter 5

LINE ATOMIC PARAMETERS

5.1 Overview

Many atomic physics quantities describe how matter and light interact. This section goes over these quantities and how they are related to one another. The inter-relations between these quantities are described in most spectroscopy texts, at about the same depth as is given below. [Hilborn \(1982\)](#) gives a far more formal description, often tracing quantities back to basic E&M concepts. Highly recommended.

5.2 Spectroscopic notation

A great deal of confusion exists over the difference between the designation of a spectrum and an ion. “Atom II” denotes a spectrum, a collection of photons, while “Atom⁺” denotes a baryon, the element “Atom” with a single electron removed.

Much of the notation in today’s atomic physics was developed in the second half of the 19th century. Physicists noticed that the spectrum of a gas would change dramatically when it was heated to high temperatures. They did not understand the reason why this happened, the electron had not yet been discovered, but they developed the notation that “Atom I” was the normal spectrum, this spectrum changed to “Atom II” when the gas was heated, and became the “Atom III” spectrum if heated still further. The “Atom II” spectrum was often called the “enhanced” spectrum of Atom. This is the reason why, in classical novae, the appearance of broad absorption lines of singly ionized species is called the “diffuse enhanced phase”.

The electron was discovered well after this notation had been developed. By the early 20th century it was understood that the “I” spectrum was produced by the atom, Atom⁰. At high temperatures the first ion, Atom⁺, formed and produced the “Atom II” spectrum.

During the first half of the 20th century astrophysicists mainly studied stellar absorption lines. This led to the commonly-used notation that the “Atom II” spectrum, for instance, measured Atom⁺. It is unambiguously true that the equivalent width of an Atom II absorption line is proportional to the column density of Atom⁺. However there is an ambiguity in emission lines. The L α H I line can be produced by impact excitation of H⁰ or by recombination of H⁺. In both cases the line is an H I line, but H I is produced by either H⁰ or H⁺, depending on details.

To be unambiguously correct you should refer to Atom I or Atom II when discussing the

spectrum. When discussing a column density or particle density you should refer to the ion, as in Atom^0 or Atom^+ . It is not correct to refer to the column density of H I. The $L\alpha$ H I emission line measures the column density of either H^0 or H^+ , depending on whether the line forms by impact excitation or recombination. The notation is not ambiguous in absorption lines, which is probably why we have such confusion today. Be unambiguous and correct - use the right notation!

5.3 Line absorption

5.3.1 Line optical depths

The optical depth for a transition $u - l$, where u and l are the upper and lower levels, is given by

$$d\tau_{l,u} = \alpha_v (n_l - n_u g_l / g_u) f(r) dr \text{ [Napier]}. \quad (5.1)$$

Here $f(r)$ is the filling factor and α_v is the atomic absorption cross section [cm^2].

The term in parenthesis is the population [cm^{-3}] of the lower level, with a correction for stimulated emission. This term is the only place where stimulated emission enters in the radiative balance equations (Elitzur et al., 1983).

5.3.2 Oscillator strengths

The oscillator strength f is a dimensionless number of order unity that can be thought of as a correction factor to make the expression for a classical oscillator agree with the quantum mechanical value. Sections below relate the oscillator strength to other line parameters such as the absorption coefficient and the transition probability. The absorption (f_{abs} , called $f_{l,u}$ here) and emission (f_{em} , called $f_{u,l}$) oscillator strengths are related by

$$g_l f_{l,u} = -g_u f_{u,l} \quad (5.2)$$

where the g 's are the statistical weights. This product is symmetric, neglecting sign, and the code tries to use gf 's throughout. The convention is that emission lines have negative oscillator strength.

5.3.3 Absorption cross section

The absorption cross section [cm^2] for a line is related to the dimensionless absorption oscillator strength f_{lu} or f_{abs} by

$$\begin{aligned} \alpha_v(x) &= \frac{\pi^{1/2} q_e^2 \lambda_{l,u}}{m_e c u_{\text{Dop}}} \phi_v(x) \\ &= 0.014974 f_{l,u} \frac{\lambda_{\text{cm}}}{u_{\text{Dop}}} \phi_v(x) = 1.4974 \times 10^{-6} f_{l,u} \lambda_{\mu\text{m}} \frac{\phi_v(x)}{u_{\text{Dop}}} \end{aligned} \quad [\text{cm}^2] \quad (5.3)$$

with the relative line displacement given by

$$x \equiv \frac{v - v_o}{\Delta v_{\text{Dop}}}, \quad (5.4)$$

$\phi_V(x)$ is the Voigt function, and u_{Dop} is the Doppler velocity width (cm s^{-1}), the point where the line profile falls to $1/e$ of its peak. With this definition of the relative line displacement, the line profile due to thermal motions alone is $\exp(-x^2)$. The constant part of equation 5.3 (i.e., everything except the rightmost term) is evaluated in routine *abscf*.

The Doppler width for thermal broadening of an atom with atomic mass A is

$$u_{\text{Dop}} = \left(\frac{2kT}{m} \right)^{1/2} [\text{cm s}^{-1}] = 12.85 \left(\frac{T}{10^4 A} \right)^{1/2} [\text{km s}^{-1}] \quad (5.5)$$

(equation 9-35 of Mihalas (1970)).

5.4 The line profile function

5.4.1 Velocities in a thermal distribution

The distribution function for a Maxwellian velocity distribution is given by

$$\frac{n(u) du}{n} = \frac{1}{\pi^{3/2}} \exp[-u^2 m_A / 2kT] \left(\frac{m}{2kT} \right)^{3/2} 4\pi u^2 du [\text{cm s}^{-1}] \quad (5.6)$$

(Novotny, 1973; p 122). There are three mean speeds in a thermal velocity distribution. The **most probable speed** is the peak of the velocity distribution, with a value

$$u_{\text{mean}}^2 = 2kT / m_A [\text{cm}^2 \text{s}^{-2}]. \quad (5.7)$$

This is found by setting the derivative of the distribution function to zero (Novotny, 1973, p 122). The velocity distribution function can be expressed in terms of the **mean speed** as

$$\frac{n(u) du}{n} = \frac{1}{\pi^{3/2}} \exp[-u^2 / u_{\text{mean}}^2] \frac{4\pi u^2}{u_{\text{mean}}^3} du [\text{cm s}^{-1}]. \quad (5.8)$$

The **average speed** is obtained by averaging over this function and is given by

$$u_{\text{average}}^2 = 8kT / \pi m_A [\text{cm}^2 \text{s}^{-2}]. \quad (5.9)$$

The **thermal Doppler velocity width** is the velocity averaged over the projected line of sight, given by (Novotny, 1973; p 204)

$$u_{\text{th}}^2 = 2kT / m_A [\text{cm}^2 \text{s}^{-2}]. \quad (5.10)$$

This is the distance from line center where the line profile falls to e^{-1} of its central value. So it turns out that the most probable speed is equal to the Doppler velocity width.

The **velocity dispersion** σ is

$$\sigma = u / \sqrt{2} [\text{cm s}^{-1}] \quad (5.11)$$

and appears in the Gaussian profile function as

$$\phi(\delta u) = \exp\left(-\delta u^2 / 2\sigma^2\right). \quad (5.12)$$

5.4.2 Micro vs macro turbulence

Micro-turbulence (hereafter, just turbulence) is due to any additional motions that occur over scales that are smaller than a photon mean free path. Micro-turbulence changes the line transfer since the line opacity is distributed over a broader range of velocities. Macro-turbulence is due to motion that occurs over such large scale lengths that they not change the optical depth through the emitting region. An example might be cloud orbital motions. The transfer within a cloud is not changed by its bulk motion and so would be considered macro-turbulence.

5.4.3 Line Widths

If a non-thermal micro-turbulent component of motions is present then equation 5.3, the total Doppler velocity width [cm s^{-1}] including turbulence, is given by

$$u_{tot}^2 = 2kT/m_A + u_{turb}^2 \quad [\text{cm}^2 \text{s}^{-2}] \quad (5.13)$$

as determined by the local kinetic temperature T . Within the code the micro-turbulent velocity u_{turb} is assumed to be zero unless it is reset with the **turbulence** command.¹

In *GetDopplerWidth* the Doppler velocity width is evaluated as

$$u_{Dop} = \sqrt{2kT/m_A + u_{turb}^2} = \sqrt{1.651 \times 10^8 T/m_{AMU} + u_{turb}^2} \quad [\text{cm s}^{-1}]. \quad (5.14)$$

The atomic weight is in atomic mass units.

The Doppler velocity width is related to the half width at half maximum by (Novotny, 1973, eqns 5-18; p 205)

$$\Delta u_{1/2} = (\ln 2)^{1/2} u_{Dop} = 0.832555 u_{Dop} \quad [\text{cm s}^{-1}] \quad (5.15)$$

and the FWHM is given by

$$\Delta u_{FWHM} = 2(\ln 2)^{1/2} u_{Dop} \quad [\text{cm s}^{-1}]. \quad (5.16)$$

5.4.4 The Doppler b parameter

Much of the literature refers to the Doppler b parameter. This is the Doppler velocity width or velocity dispersion with turbulence included, and is given by

$$b^2 = u_{Dop}^2 = 2kT/m_A + u_{turb}^2 \quad [\text{cm}^2 \text{s}^{-2}]. \quad (5.17)$$

With these definitions

$$b = u_{Dop} = \Delta u_{FWHM} / [2(\ln 2)^{1/2}] \quad [\text{cm s}^{-1}]. \quad (5.18)$$

¹Note that the **turbulence** command accepts u_{turb} in km s^{-1} but converts it into cm s^{-1} , the units used throughout the code.

5.4.5 Voigt function

By combining equations 5.1 and 5.3 we can define the optical depth a relative displacement x away from line center as:

$$\tau_v(x) = \int_{R_{\text{in}}}^{R_{\text{out}}} \frac{\pi^{1/2} q_e^2 \lambda f_{l,u}}{m_e c u_{\text{Dop}}} \varphi_v(x) (n_l - n_u g_l / g_u) f(r) dr. \quad (5.19)$$

Using this equation, the line center optical depth τ_0 can be defined as $\tau_0 \equiv \tau_v(0)$. The relative displacement x is given by equation 5.4 above. In our formalism, the Voigt function is normalized such that the integral is $\sqrt{\pi}$. A schematic approximation for the Voigt function is given by equation 9-61 of [Mihalas \(1978\)](#)

$$\varphi_v(x) \approx \exp(-x^2) + a/(\pi^{1/2} x^2). \quad (5.20)$$

Here a is the damping constant. This expression cannot be used in real calculations as it goes to infinity for $x = 0$, but it does convey the general behavior of the Voigt function where for small x it looks like a Gaussian function while for large x it resembles a Lorentzian profile. In CLOUDY we use an enhanced version of the *humlik* algorithm ([Wells, 1999](#)) to calculate the Voigt function to a relative precision of at least 2.5×10^{-3} for all values of a and x . For most values of a , the relative accuracy will be better than 10^{-4} though. The value at line center is given by:

$$\varphi_v(0) = 1 - \frac{2a}{\sqrt{\pi}} + a^2 + O(a^3) \quad (a \rightarrow 0). \quad (5.21)$$

The line center optical depth thus depends on a , or more generally on the shape of the line profile, while the mean optical depth does not.

5.4.6 Mean vs. line center optical depths

CLOUDY internally works with line center optical depths throughout (see, for example, [Mihalas, 1978](#)). However, mean optical depths are reported in the final printout. Since CLOUDY treats line overlap and also integrates the line optical depth through a medium where the Doppler width will generally be varying, it is not straightforward to convert the line center optical depths used internally to a mean optical depth. To avoid these difficulties, we report a mean optical depth that is exactly a factor $\sqrt{\pi}$ times *larger* than the line center optical depth. This assumes that the Voigt function at line center is $\varphi_v(0) \approx 1$. This approximation is OK when the damping parameter a is small, $a \ll 1$ (see equation 5.21), which is generally the case in the IR, optical, and UV wavelength range. However, this approximation breaks down in the X-ray regime where a can be much larger.

5.5 The Einstein coefficients

The dimensionless oscillator strength gf is related to the transition probability A_{ul} [s^{-1}] by

$$g_l f_{l,u} = g_u f_{u,l} = \frac{m_e c \lambda_{cm}^2}{8 \pi^2 q_e^2} g_u A_{u,l} = 1.4992 g_u A_{u,l} \lambda_{cm}^2 = 1.4992 \times 10^{-8} g_u A_{u,l} \lambda_{\mu\text{m}}^2 \quad (5.22)$$

where $\lambda_{\mu m}$ is the wavelength in microns and λ_{cm} the wavelength in centimeters. The absorption oscillator strength is related to the transition probability by

$$f_{l,u} = \frac{m_e c \lambda_{cm}^2}{8\pi^2 q_e^2} \frac{g_u}{g_l} A_{u,l} = 1.4992 \times 10^{-8} A_{u,l} \lambda_{\mu m}^2 \frac{g_u}{g_l} \quad (5.23)$$

or

$$A_{u,l} = \frac{8\pi^2 q_e^2}{m c \lambda_{cm}^2} \frac{g_l}{g_u} f_{abs} = \frac{f_{l,u}}{1.4992 \times 10^{-8}} \lambda_{\mu m}^{-2} \frac{g_l}{g_u} \quad [s^{-1}]. \quad (5.24)$$

Combining equations 5.3 and 5.23 we obtain an expression relating the transition probability and the absorption cross section;

$$\begin{aligned} \alpha_v &= \frac{\lambda^3 g_u}{8\pi g_l} \frac{A_{u,l}}{\pi^{1/2} u_{Dop}} \phi_v(x) \\ &= \frac{\lambda^3 g_u}{8\pi g_l} \frac{A_{u,l}}{\pi^{1/2} u_{Dop}} \phi_v(x) \quad [cm^2]. \\ &= 2.24484 \times 10^{-14} A_{u,l} \lambda_{\mu m}^3 \frac{g_u}{g_l} \frac{\phi_v(x)}{u_{Dop}} \end{aligned} \quad (5.25)$$

The coefficient for induced emission, B_{ul} , is related to A_{ul} by the phase space factor $2h\nu^3/c^2$;

$$A_{u,l} = \frac{2h\nu^3}{c^2} B_{ul} \quad [s^{-1}] \quad (5.26)$$

and the induced emission and absorption probabilities are related by

$$g_l B_{l,u} = g_u B_{u,l} \quad (5.27)$$

The absorption cross section α_v is related to $B_{l,u}$ by

$$\alpha_v = \frac{hc}{4\pi^{3/2}} \frac{B_{l,u}}{u_{Dop}} \phi_v(x) \quad [cm^2]. \quad (5.28)$$

In these terms the optical depth increment (equation 5.1) is given by

$$\begin{aligned} d\tau_{l,u} &= \alpha_v (n_l - n_u g_l/g_u) f(r) dr \\ &= \frac{hc}{4\pi^{3/2}} \frac{B_{l,u}}{u_{Dop}} \phi_v(x) (n_l - n_u g_l/g_u) f(r) dr. \end{aligned} \quad (5.29)$$

5.6 Continuum pumping

5.6.1 Photon occupation number

The intensity of a radiation field can be thought of as two parts, the available volume of phase space $2h\nu^3/c^2$ and a dimensionless occupation number η giving the fraction of that space that is filled. Occupation numbers can be larger than unity for photons, which are Bose-Einstein particles.

For reference, the Planck function is given by

$$B_\nu = I_\nu = \frac{F_\nu}{\pi} = \frac{2h\nu^3}{c^2} \frac{1}{\exp(h\nu/kT) - 1} \quad [erg \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ Hz}^{-1}] \quad (5.30)$$

where F_ν is the single-hemisphere emittance from an opaque surface. The photon occupation number of a blackbody is then

$$\eta_\nu = \frac{1}{\exp(h\nu/kT) - 1} \quad (5.31)$$

The dimensionless occupation number for any continuum with a mean intensity J_ν ($\text{erg cm}^{-2} \text{ s}^{-1} \text{ Hz}^{-1} \text{ sr}^{-1}$) at a frequency ν is defined as

$$\eta_\nu \equiv J_\nu / (2h\nu^3/c^2) \equiv [\exp(h\nu/kT_{ex}) - 1]^{-1}. \quad (5.32)$$

Here T_{ex} is the excitation temperature of the continuum at the frequency.

5.6.2 Pumping rates

Continuum fluorescence is treated as in [Ferland and Rees \(1988\)](#) and [Ferland \(1992\)](#). The rate of induced radiative excitation by continuum photons (continuum pumping) is given by

$$r_{l,u} = n_l B_{l,u} J_{l,u} = n_l A_{u,l} \frac{J_{l,u}}{2h\nu^3/c^2} \frac{g_u}{g_l} = n_l A_{u,l} \eta_\nu \frac{g_u}{g_l} \quad [\text{cm}^{-3} \text{ s}^{-1}] \quad (5.33)$$

where η_ν is the dimensionless continuum occupation number at the line energy. The rate of induced radiative de-excitation is related by detailed balance and is given by

$$r_{u,l} = r_{l,u} \frac{g_l}{g_u} \quad [\text{cm}^{-3} \text{ s}^{-1}]. \quad (5.34)$$

The occupation number has the advantage that the Einstein B 's do not enter any rate equations. All radiative rates can be expressed in terms of an A and ν .

5.6.3 Optical depth effects

The line becomes self-shielding when the optical depth is greater than unity. The line optical depth between the current position and the illuminated face of the slab is used to evaluate the inward-looking escape probability, the probability that a line photon will travel this distance in a single scattering. Line optical depths do not directly affect η_c , only continuous opacities do. The final form of the continuum pumping rate is

$$r_{l,u} = n_l A_{u,l} \eta_\nu \frac{g_u}{g_l} \gamma_{l,u}(\tau) \quad [\text{cm}^{-3} \text{ s}^{-1}] \quad (5.35)$$

where $\gamma_{l,u}$ is the probability that continuum photons penetrate an optical depth τ_o and are then absorbed by an atom:

$$\gamma_{l,u} = \int_0^\infty \phi_\nu \exp(-\tau_o \phi_\nu) d\nu / \int_0^\infty \phi_\nu d\nu. \quad (5.36)$$

where ϕ_ν is the Voigt function. Figure 5.1, taken from [Ferland \(1992\)](#), shows $\gamma_{l,u}$ for a wide variety of values of the damping constant a .

Figure 5.1: This figure shows the probability that a photon will penetrate to the line center optical depth shown on the x-axis, and then be absorbed by the line. The curves are for various values of the damping constant a (the ratio of damping width to Doppler width), as indicated on the figure.

The code works in terms of the flux of photons per energy mesh point. The transmitted continuum has a flux of photons φ_ν (photons $\text{cm}^{-2} \text{s}^{-1} \text{Ryd}^{-1}$). The photon occupation number of the attenuated continuum is given by equation 5.31 above, here written as

$$\eta_\nu = \varphi_\nu \frac{c^2}{8\pi \nu_1^3 \nu_{\text{Ryd}}^2} \quad (5.37)$$

where ν_{Ryd} is the frequency in Rydbergs, ν_1 is the frequency of 1 Rydberg, and the other symbols have their usual meaning. Continuum pumping is included among the general line excitation processes for all lines considered by the code.

5.7 Kirchhoff's Law

Kirchhoff's law is the statement that, in thermodynamic equilibrium, the energy emitted is equal to the energy absorbed. If the emission and absorption coefficients are j_ν and κ_ν then

$$j_\nu = \kappa_\nu B_\nu(T) \quad (5.38)$$

where $B_\nu(T)$ is Planck's function.

5.8 The line source function and mean intensity

The source function for a line is defined as

$$S_l(T_{\text{exc}}) \equiv B_l(T_{\text{exc}}) \equiv \frac{j_l}{\kappa_l} = \frac{A_{u,l} n_u}{B_{l,u} (n_l - n_u g_l / g_u)} \quad [\text{erg Hz}^{-1} \text{sr}^{-1} \text{s}^{-1}]. \quad (5.39)$$

where T_{exc} is the line excitation temperature

$$\frac{n_u/g_u}{n_l/g_l} = \exp[-h\nu/kT_{\text{exc}}] \quad (5.40)$$

$B_l(T_{\text{exc}})$ is the Planck function at the line excitation temperature and the line emission and absorption coefficients j_l and κ_l enter through Kirchhoff's law. Combining with the definitions of the Einstein relations we find the relation

$$S_l(T_{\text{exc}}) = \frac{2h\nu^3}{c^2} \frac{n_u/g_u}{(n_l/g_l - n_u/g_u)} \quad [\text{erg Hz}^{-1} \text{sr}^{-1} \text{s}^{-1}]. \quad (5.41)$$

The radiation field within the line is given by the mean intensity \bar{J} . \bar{J} and S_l are related by the net radiative bracket, which we approximate as the escape probability P_{esc} :

$$P_{\text{esc}} \equiv 1 - \bar{J}/S_l. \quad (5.42)$$

The mean intensity is then give by

$$\bar{J} = S_l (1 - P_{\text{esc}}). \quad (5.43)$$

and the line center photon occupation number is

$$\eta_l = \frac{n_u/g_u}{(n_l/g_l - n_u/g_u)} (1 - P_{\text{esc}}). \quad (5.44)$$

5.9 Level populations in radiative equilibrium limit

For a two-level system where collisions can be neglected, in the optically thin limit, the balance equation relating the populations of a two-level system is given by

$$\frac{dn_u}{dt} = n_l B_{lu} J - n_u (A_{ul} + B_{ul} J) \quad [\text{cm}^{-3} \text{ s}^{-1}]. \quad (5.45)$$

In the time-steady limit, where the time derivative is zero, the balance can be rewritten in terms of the transition probabilities as

$$n_u (A_{ul} + A_{ul} \eta) = n_u A_{ul} (1 + \eta) = n_l A_{ul} \eta \frac{g_u}{g_l} \quad [\text{cm}^{-3} \text{ s}^{-1}]. \quad (5.46)$$

In the limit where η is small every photoexcitation is followed by spontaneous decay, while in the limit where η is large the level populations are given by the ratio of statistical weights, i.e., T_{exc} is infinite.

Chapter 6

LINE DETAILS

6.1 Overview

The effects of optical depths, continuum pumping, collisions, and destruction by background opacity, are computed for *all* permitted and intercombination lines. The cooling is usually distributed among many lines in high-density models, and these lines are usually optically thick. This section describes the methods and data structures used within the code to accomplish this.

6.2 Line Boltzmann factors

The Boltzmann factor $h\nu/kT$ for a line with a known wavelength or energy is given by Table 6.1. The table lists the ratio $h\nu/k$ for various units of the line energy. Vacuum, not air, wavelengths, must be used for all quantities involving wavelengths.

6.3 Air vs vacuum wavelengths

The convention across physics and astronomy is to give line wavelengths in vacuum for $\lambda \leq 2000 \text{ \AA}$ and in air for $\lambda > 2000 \text{ \AA}$. There is no choice—if you observe visible light with HST the wavelengths must be quoted in air.

Air wavelengths are smaller than vacuum wavelengths because the wavefronts are crushed as then enter the denser medium with its higher index of refraction. The frequency is unchanged.

Table 6.1: Line Boltzmann Factors	
Line Energy Units	$h\nu/k$ (K)
Angstroms	$1.43877(+8)/\lambda(\text{\AA})$
microns	$1.43877(+4)/\lambda(\mu)$
wavenumbers	$1.43877 \times \sigma$
Rydbergs	$1.5788866(+5) \times E$

6.4 The line escape probability functions

6.4.1 Escape probability formalism vs exact radiative transfer

Radiative transport effects are approximated with the escape probability formalism (EPF). This includes line pumping by the incident continuum, photon destruction by collisional deactivation or by continuous opacities, and line overlap in special cases. This section describes how the escape probability is related to the net radiative bracket, the formally correct term in the transfer equation.

The full balance equation for radiative losses and gains for the upper level of a two level atom is given by

$$n_u A_{ul} + n_u B_{ul} \bar{J} - n_l B_{lu} \bar{J} \equiv n_u A_{ul} \rho_{ul} \approx n_u A_{ul} P_{ul} \quad (6.1)$$

where A and B are the Einstein coefficients, \bar{J} is the mean intensity averaged over the line, and ρ_{ul} is the net radiative bracket, defined as

$$\rho_{ul} \equiv 1 - \bar{J}/S \quad (6.2)$$

where S is the line source function. The essence of the EPF is to replace ρ_{ul} with the escape probability P_{ul} on the argument that the difference between J and S is due to photons leaking away from the region. (Elitzur et al., 1983; Sec 2.6) shows that this is exact if S is constant across the line-forming region. In the code ρ_{ul} is replaced with P_{ul} .

6.4.2 Redistribution functions

At low densities, line scattering for a two-level atom is coherent in the atom's reference frame and the line profile function is described by the incomplete redistribution function. At high densities the Stark effect can broaden the line. When the radiation density is high, scattering within excited states can inhibit the broadening of resonance lines such as $L\beta$ (line interlocking), destroying the coherence of the scattering process. In these cases complete redistribution in a Doppler core more closely describes the scattering process.

CLOUDY uses several escape probability functions to take these processes into account. Strong resonance lines are treated with partial redistribution with a Voigt profile. Subordinate lines are treated with complete redistribution in a Doppler core.

6.4.3 Incomplete redistribution

Incomplete redistribution is assumed for resonance transitions such as C IV $\lambda 1549$ and the $L\alpha$ transitions of hydrogen and helium. Two studies of line formation using this approximation are those of Bonilha et al. (1979) and Hummer and Kunasz (1980). Both studies suggest escape probabilities of the form

$$P_l(\tau) = \{1 + b(\tau) \tau\}^{-1} \quad (6.3)$$

but there is substantial disagreement in the form and value of the factor $b(\tau)$, sometimes by more than a factor of 2. (This is after due allowance for the different definitions of line opacities in the two papers.) CLOUDY uses the Hummer and Kunasz (1980) results for H I, He I, and He II $L\alpha$ and strong resonance lines such as C IV $\lambda 1549$. Their tabulated values were fitted by interpolation.

6.4.4 Damping constant

The damping constant a is given by

$$a = \frac{\Gamma}{4\pi \Delta\nu_D} = \frac{\lambda_{cm} \Sigma A}{4\pi u_{Dop}} = \frac{\lambda_{cm} 7.958 \times 10^{-2} \Sigma A}{u_{Dop}} = \frac{\lambda_{\mu m} 7.958 \times 10^{-6} \Sigma A}{u_{Dop}} \quad (6.4)$$

where Γ is the inverse lifetime of the level (the sum of the A 's from the upper level), $\Delta\nu_D$ is the Doppler width in frequency units (Mihalas, 1978), λ_{cm} and $\lambda_{\mu m}$ are the wavelengths in cm and microns respectively, and u_{Dop} is the Doppler width in cm s^{-1} . The ratio $\Gamma\lambda/4\pi$ is stored in the line structures and the a 's are evaluated using this ratio and the current Doppler width.

6.4.5 Background opacity and Destruction probability

The ratio of continuous to total opacity is X_c parameterized as

$$X_c = \frac{\sum \kappa_c n_c}{\kappa_l n_l + \sum \kappa_c n_c} \quad (6.5)$$

where the κ_l 's are the line center absorption opacities and the n 's the number of absorbers.

6.4.6 Complete redistribution

Lines arising from excited states (hydrogen Balmer, Paschen, etc.) and Lyman lines with $n_u > 2$ are treated assuming complete redistribution in a Doppler core (i.e., the damping constant a is assumed to be zero). This assumption can be changed with the **atom redistribution** command. If the total optical depth of the slab is T , then the escape probability at a depth τ from the illuminated face is given by;

$$P_{u,l}(\tau, T, X_c) = [1 - X_c F(X_c)] \frac{1}{2} [K_2(\tau, X_c) + K_2(T - \tau, X_c)] \quad , \quad (6.6)$$

and the destruction probability is

$$D_{u,l}(X_c) = X_c F(X_c). \quad (6.7)$$

The function is

$$F(X_c) = \int_{-\infty}^{\infty} \frac{\varphi(x)}{X_c + \varphi(x)} dx, \quad (6.8)$$

where in these expressions (and in this part of the code) the *mean opacity is used*, and $\varphi(x) \approx \pi^{1/2} \exp(-x^2)$ is the Voigt function. $F(X_c)$ is interpolated from the tables presented by Hummer (1968). The function

$$K_2(\tau, X_c) \equiv \frac{1}{1 - X_c F(X_c)} \int_{-\infty}^{\infty} \frac{\varphi^2(x)}{X_c + \varphi(x)} E_2[(X_c + \varphi(x)) \tau] d\tau \quad (6.9)$$

is evaluated numerically.

The complete redistribution escape probabilities are corrected for finite damping parameters by including a separate wing escape probability. The resulting total escape probabilities have been

tested against numerical integrations of the exact formulae in [Avrett and Loeser \(1966\)](#); [Hummer and Rybicki \(1982\)](#) – note the different definitions of K_2 in these papers – verified by comparison by the tabulations and fits in these papers. The overall fit to the escape probability is in error by at most 25% in the range $a = 10^{-3}$ – 10^3 , with the largest error at $\tau \simeq 1$, and correct asymptotic behaviour in the low τ and high τ limits. This level of accuracy is thought to be sufficient, given the other approximations inherent in the escape probability method.

6.4.7 Masing lines

A line maser when its optical depth is negative. The escape probability is ([Elitzur, 1992](#); p 32, see also [Elitzur, 1990a,b](#))

$$P_{u,l} = \frac{1 - \exp(-\tau)}{\tau}. \quad (6.10)$$

The code will generate a comment if strong maser action occurs for any transition.

6.4.8 Stark broadening

Distant collisions with charged particles broaden the upper levels of lines, and in the limit of very high densities this will make the scattering process completely non-coherent even for $L\alpha$ (i.e., complete redistribution obtains). Cloudy closely follows the treatment of [Puetter \(1981\)](#) in treating Stark broadening.

6.4.9 Net escape probability

A total escape probability $P_{l,tot}$, given by

$$P_{u,l} = \min(P_{inc} + P_{Stark}, P_{com}), \quad (6.11)$$

is defined for transitions described by incomplete redistribution. The escape probabilities are those for incomplete, Stark, and complete redistribution respectively. The total effective escape probability is not allowed to exceed the complete redistribution value for $\tau > a^{-1}$.

If τ is the optical depth in the direction towards the source of ionizing radiation and T is the total optical depth computed in a previous iteration, then the escape probability entering the balance equations is

$$P_{u,l}(\tau, T) = \{P_{u,l}(\tau) + P_{u,l}(T - \tau)\} / 2. \quad (6.12)$$

In general the total optical depth T is only known after the first iteration, so more than one iteration must be performed when radiative transfer is important.

6.5 Optical depths and the geometry

The terms open and closed geometry are defined in a section in Part I. The treatment of transfer in these two limits is described here.

6.5.1 Open geometry

This is the default. During the first iteration the line optical depth is defined using only optical depths accumulated in the inward direction. This optical depth is initialized to a very small number at the start of the calculation. At the end of the first iteration the total optical depth is set to the optical depth accumulated in the inward direction. At the end of subsequent iterations the total optical depth is defined as a mean of the new and old inward optical depths.

6.5.2 Closed geometry overview

Continuum photons are assumed to interact with gas fully covering the continuum source. At the end of the first iteration the total continuum optical depths are set equal to twice the computed optical depths, and the inner optical depths reset to the computed optical depths. The same recipe is followed on subsequent iterations, except that means of old and newly computed optical depths are used.

Closed expanding geometry This is the default if the **sphere** command is entered. In this case it is assumed that line photons do not interact with lines on the “other” side of the expanding spherical nebula. The treatment of line optical depths is entirely analogous to that described for an open geometry, since the presence of the distant material has no effect on line transfer.

Closed static geometry This is assumed if the **sphere static** command is entered. In this case line photons from all parts of the spherical shell do interact. As a result the optical depth scale is poorly defined on the first iteration, and more than one iteration is required. On second and later iterations the total line optical depth is set to twice the optical depth of the computed structure, and the optical depth at the illuminated face of the shell is set to half of this. The optical depth scale is only reliably defined after at least a second iteration.

6.5.3 Wind

The model is a large velocity gradient ($v \propto R$ Sobolev approximation) wind. This is described further in Part 2 of this document.

6.6 Collision strengths

I have tried to follow the Opacity Project notation throughout this document ([Lanzafame et al., 1993](#)). The energy-specific collision strength Ω_{lu} for a transition between upper and lower levels u and l is related to the excitation cross section Q_{lu} by

$$Q_{lu} = \frac{\pi \Omega_{lu}}{g_l k_{lu}^2} \quad [\text{cm}^2] \quad (6.13)$$

where k_{lu}^2 is the wavenumber of the collision energy. If the collisions are with thermal electrons having a Maxwellian velocity distribution $f(u)$ and velocity u then the rate coefficient q_{lu} is given by

$$q_{lu} = \int_0^\infty f(u) u Q_{lu} du = \frac{2\pi^{1/2} \hbar^2}{g_l m_e} a_o \left(\frac{R_\infty}{kT} \right) \Upsilon_{lu} \exp \left(-\frac{E_{lu}}{kT} \right) \sqrt{\frac{2kT}{m_e}} \quad [\text{cm}^3 \text{s}^{-1}]. \quad (6.14)$$

E_{ul} is the transition energy in Rydbergs, a_o is the Bohr radius,

$$a_o = \frac{\hbar^2}{m_e q_e^2} = 0.529177249 \times 10^{-8} \text{ cm} \quad (6.15)$$

and R_∞ is the Rydberg energy. Then the thermally-averaged collision strength is given by

$$\Upsilon_{lu} = \int_0^\infty \Omega_{lu} \exp\left(-\frac{\epsilon}{kT}\right) d\left(\frac{\epsilon}{kT}\right). \quad (6.16)$$

The rate coefficient for collisional de-excitation is then given by

$$q_{ul} = \frac{\Upsilon}{g_u \sqrt{T_e}} \left(\frac{2\pi}{k}\right)^{1/2} \frac{\hbar^2}{m_e^{3/2}} = \frac{\Upsilon 8.6291 \times 10^{-6}}{g_u \sqrt{T_e}} \quad [\text{cm}^3 \text{s}^{-1}]. \quad (6.17)$$

The rate coefficient for excitation follows from detailed balance:

$$q_{lu} = q_{ul} \frac{g_u}{g_l} \exp(-\chi) = \frac{\Upsilon 8.6291 \times 10^{-6}}{g_l \sqrt{T_e}} \exp(-\chi) \quad [\text{cm}^3 \text{s}^{-1}]. \quad (6.18)$$

6.7 Born approximation

The Born approximation is valid for energies much larger than the excitation energy of the transition. The energy specific collision strength is given by [Bethe \(1930\)](#) as

$$\Omega_{lu} \approx \frac{4g_l f_{lu}}{E_{lu}} \ln\left(\frac{4\epsilon}{E_{lu}}\right) \quad (6.19)$$

where $f_{l,u}$ is the absorption oscillator strength of the permitted transition.

6.8 The g-bar approximation

The g-bar or [van Regemorter \(1962\)](#) approximation relates the collision strength to the transition probability A_{ul} and wavelength λ (in μm). Here, the collision strength for the downward transition Υ_{ul} is approximately given by

$$\begin{aligned} \Upsilon_{u,l} &= \frac{2\pi}{\sqrt{3}} \frac{m^2 e^2}{h^3} \lambda_{\mu m}^3 10^{-12} g_u A_{u,l} \bar{g} \\ &\approx 2.388 \times 10^{-6} \lambda_{\mu m}^3 g_u A_{u,l} \bar{g} \\ &\approx 159 \lambda_{\mu m} g_l f_{abs} \bar{g} \end{aligned} \quad (6.20)$$

where g_u and g_l are the statistical weights of the upper and lower levels and f_{abs} is the absorption oscillator strength. For energies of interest in astrophysical plasmas, where $kT < h\nu$, \bar{g} is approximately given by

$$\bar{g} \approx \begin{cases} 0.2; & \text{positive ions} \\ (kT/h\nu)/10; & \text{neutrals} \end{cases} \quad (6.21)$$

(van Regemorter 1962). These approximations are generally accurate to better than 1 dex. [Gaetz and Salpeter \(1983\)](#) give improved forms of the approximation.

6.9 The critical density

The critical density is defined as the density at which the radiative de-excitation rate $A_{ul}P_{ul}$ (where A is the transition probability and P is the escape probability) equals the collisional de-excitation rate $q_{ul}n_e$. Setting

$$A_{ul}P_{ul} = C_{ul} = q_{ul}n_e = \Upsilon \frac{8.629 \times 10^{-6}}{g_u \sqrt{T_e}} n_e \quad [\text{s}^{-1}] \quad (6.22)$$

where Υ is the thermally averaged collision strength, the critical density is given by

$$n_{crit} \sim \frac{A_{ul}P_{ul}g_u\sqrt{T_e}}{\Upsilon 8.629 \times 10^{-6}} \quad [\text{cm}^{-3}]. \quad (6.23)$$

For an optically allowed transition, in which the g -bar approximation may apply, this density is approximately given by

$$n_{crit} = \frac{4.8 \times 10^{10} \sqrt{T_e}}{\lambda_{\mu m}^3 \bar{g}} \quad [\text{cm}^{-3}]. \quad (6.24)$$

6.10 Line thermalization length

Line radiative transfer will affect the thermal equilibrium of the gas when the collision time scale approaches an effective lifetime $\tau \sim (A_{ul}/n_{scat})^{-1}$, where A_{ul} is the transition probability and n_{scat} is the number of scatterings a line photon undergoes before escape. For permitted metal lines (which often have optical depths $\sim 10^4 - 10^6$) line thermalization becomes important at densities $n_e > 10^{15}/\tau 10^{10} \text{cm}^{-3}$. These effects are important for hydrogen at considerably lower densities due to its greater abundance. Additionally, continuum transfer affects the ionization and thermal equilibrium of the gas at all densities.

6.11 Averaging levels into terms

6.11.1 Collision strengths

Often cases are encountered in which a multiplet consisting of many lines can be treated as the equivalent two-level atom with a single transition. In these cases it is necessary to define “effective” collision strengths and transition probabilities. If the collision strength from an individual level i is Υ_i , and the statistical weights of the level and term are g_i and g_{tot} respectively, then the effective collision strength Υ_{eff} is related to Υ_i by a simple argument. The collision rate q_i is proportional to the ratio

$$n_i q_i \propto n_i \frac{\Upsilon_i}{g_i} \quad [\text{s}^{-1}] \quad (6.25)$$

so that

$$n_{tot} q_{tot} = \sum_i n_i q_i \propto \sum_i n_i \frac{\Upsilon_i}{g_i} \quad [\text{s}^{-1}]. \quad (6.26)$$

In many cases it is valid to assume that the levels within the term are populated according to their statistical weight, viz.,

$$n_i = n_{tot} \frac{g_i}{g_{tot}} \quad [\text{cm}^{-3}]. \quad (6.27)$$

Then, the effective collision strength Υ_{tot} is operationally defined by the relations

$$n_{tot} \frac{\Upsilon_{tot}}{g_{tot}} = \sum_i n_i \frac{\Upsilon_i}{g_i} = n_{tot} \sum_i \frac{g_i}{g_{tot}} \frac{\Upsilon_i}{g_i} = n_{tot} \frac{\sum_i \Upsilon_i}{g_{tot}}. \quad (6.28)$$

So, the effective collision strength of the entire multiplet is

$$\Upsilon_{tot} = \sum_i \Upsilon_i. \quad (6.29)$$

6.11.2 Transition probabilities

Under similar circumstances an effective transition probability A_{eff} may be defined as

$$n_{tot} A_{tot} = \sum_i n_i A_i = n_{tot} \sum_i \frac{g_i}{g_{tot}} A_i \quad (6.30)$$

so that the effective transition probability is

$$A_{tot} = \sum_i \frac{g_i}{g_{tot}} A_i. \quad (6.31)$$

So collision strengths are added, and transition probabilities averaged.

6.12 Level populations with collisions

Both escape and destruction probabilities enter in the calculation of a level population and line emissivity. The escape probability $P_{u,l}$ is the probability that a line photon will escape in a single scattering (Elitzur et al., 1983; Elitzur, 1984). The destruction probability $D_{u,l}$ is the probability that a line photon will be destroyed in a single scattering.

The line de-excitation rate is given by

$$\left(\frac{dn_u}{dt} \right)_{rad} = n_u A_{u,l} (P_{u,l} + D_{u,l}) - n_l A_{u,l} \eta \gamma_{u,l} + n_u C_{ul} - n_l C_{lu} \quad [\text{cm}^{-3} \text{s}^{-1}] \quad (6.32)$$

where η is the photon occupation number of the attenuated external radiation field, C is the collision rate (s^{-1}), and $\gamma_{u,l}$ is the fluorescence probability.

The net emission from a transition between the level n to a lower level l and escaping to the surface is then

$$4\pi j(n,l) = n_n A_{n,l} h\nu_{n,l} P_{u,l}(\tau_{n,l}) f(r) \quad [\text{erg cm}^{-3} \text{s}^{-1}] \quad (6.33)$$

where $f(r)$ is the filling factor. The total emission from the gas is then

$$e(n,l) = \int_V n_n A_{n,l} h\nu_{n,l} P_{u,l}(\tau_{n,l}) f(r) dV \quad [\text{erg cm}^{-2} \text{s}^{-1} \text{ or } \text{erg s}^{-1}] \quad (6.34)$$

depending on whether the intensity or luminosity case is chosen. The local cooling rate ($\text{erg cm}^{-3} \text{s}^{-1}$) due to the line is related to the level populations by

$$\Lambda_{u,l} = (n_l C_{l,u} - n_u C_{u,l}) f(r) h\nu \quad [\text{erg cm}^{-3} \text{s}^{-1}] \quad (6.35)$$

and the local flux ($\text{cm}^{-2} \text{s}^{-1}$) of “on-the-spot” (OTS) photons caused by line loss (used to compute heating or photoionization rates for the sources of the background opacity) is

$$\phi_{OTS} = \frac{n_u A_{u,l} D_{u,l}(X_c)}{\sum \kappa_c n(c)}. \quad (6.36)$$

The ratio of inward to total line intensity is then given by

$$\frac{4\pi j(in)}{4\pi j(total)} = \frac{P_{u,l}(\tau)}{[P_{u,l}(\tau) + P_{u,l}(T - \tau)]}. \quad (6.37)$$

Chapter 7

CLOUDY AS A STANDALONE PROGRAM

CLOUDY can be used to run a single model, to create large grids of calculations, or to compute a number of simulations while varying one or more parameters to match an observed spectrum. This Chapter describes how to use CLOUDY as a self-contained program to read in the parameters for the simulation and compute the result. The next Chapter discusses the case in which the code is called as a subroutine of another larger code.

7.1 Running a single model with a shell script

The code reads from an input file and can create a large number of output files. The latter include both the main output (described in Chapter 1, [OUTPUT](#)) and the ancillary “save” files (described in the Chapter 16 of Hazy 1, [CONTROLLING OUTPUT](#)).

It is a good idea to follow a naming convention for these files. The convention I use is the style “`basename.type`” where `basename` explains the astrophysical context (for instance, “quasar” or “IGM”) and `type` gives the type of information in the file. For instance, a model of a planetary nebula may have the base name “`pn_halo`”, the input script might be `pn_halo.in`, the output would be in `pn_halo.out`, and the file created by the **save overview** command might be `pn_halo.ovr`. Then all of these files could be located with a simple “`ls pn.*`” and all overview files with a “`ls *.ovr`” on a Linux system.

The `pn.in` file contains the input commands that tell the program what to do. A typical example might be the following:

```
# log of the hydrogen density (cm^-3)
hden 4
# log of the inner radius (cm)
radius 17
# black body temperature and total luminosity
black body 1e5 K, luminosity 38
save overview "pn.ovr"
```

CLOUDY stops reading the input stream when it reaches either an empty line or the end of file. Nothing special is needed at the end of the input file.

I have a shell script named `run` which is in my “bin” directory, which I include on my path. The shell script `run` consists of the following on Linux:

```
cloudy.exe < $1.in > $1.out
```

Under Windows it would have the name `run.bat` and would contain the following

```
cloudy.exe < %1.in > %1.out
```

If `run` is executed by typing

```
run pn
```

it would read the input stream in `pn.in` and create an output file called `pn.out`.

7.2 Running a single model from the command line

The code also has two command-line options that will accomplish the same thing as the shell script described in the previous section. If you create an executable called `cloudy.exe`, then the command

```
cloudy.exe model.in
```

will read input from `model.in`, write output to `model.out`, and add the prefix `model` to all the save files. This can also be written

```
cloudy.exe -p model
```

Alternatively, you can use the command

```
cloudy.exe -r model
```

which does the same thing, except that it will *not* add the prefix `model` to all the save files (mnemonic: `-p` will Prefix Save file names, while `-r` will only Redirect input and output).

By typing the command

```
cloudy.exe -h
```

you can a list of all the command line flags that CLOUDY supports. There are two additional flags, `-a` and `-g`, that are used for debugging the code and internally in grid runs. They should never be used in normal situations.

7.3 Running grids of simulations or optimizing a simulation

The greatest insight is gained by creating grids of simulations which vary one or more of the input parameters to show how various predictions change, or to optimize the agreement between the predicted and observed values. One example, the predicted C IV $\lambda 1549$ equivalent width as a function of the flux of ionizing photons and cloud density, is shown in Figure 8.1. See [Baldwin et al. \(1995c\)](#) for more details.

Such grids of simulations can be made parallel on distributed memory parallel machines because each point in the grid is independent of the other points.

7.3.1 Grids of simulations

The **grid** command is described in Chapter 18 *THE GRID COMMAND* of Hazy 1.

7.3.2 Optimizing a simulation

The **optimize** command is described in Chapter 17 *THE OPTIMIZE COMMAND* of Hazy 1.

7.4 Parallel processing with MPI

Peter van Hoof created a wrapper for the **grid** and **optimize** commands. CLOUDY will automatically run these commands using all available processors if the code is compiled with an MPI aware compiler and run on an appropriate computer.

Chapter 8

CLOUDY AS A SUBROUTINE

8.1 Overview

CLOUDY is designed to be used as a subroutine of other, much larger, codes. When used this way a series of subroutine calls, described next, are used to initialize the code, specify the initial conditions, do the simulation, and finally examine the predictions.

A common strategy is to call the code to compute line intensities for a large matrix of parameters. The results of one such calculation is shown in Figure 8.1 (Baldwin et al., 1995b; Ferland, 2003). Such grids can be computed in a few dozen hours on modern workstations, and offer far greater insight to physical effects of changing model parameters than does a single model.

Much of this can be done without writing a program, by using the **grid** command. This command was introduced by Ryan Porter in C07.02, and makes it possible to create large grids of models like those shown in Figure 8.1 with commands. The **grid** command is described in Part 1 of this document. There are several **save** output commands that are designed to save information from grid calculations.

8.1.1 Host languages

CLOUDY is written in C++, and it is assumed for most of this section that CLOUDY will be called from an external C or C++ program.

However, there is experimental support for a number of other languages.

You can call a C++ program like CLOUDY from a Fortran program by using the *cfortran.h* header file described at <http://www-zeus.desy.de/~burow/cfortran/>. I have never tried this. Good luck.

In the subdirectory `sys_gcc_shared`, an additional set of Makefile targets are set up to use the subroutine API described below for Perl and Python scripts, using the SWIG interface generator. In this directory, there is also an experimental direct interface to the Lua scripting language.

Figure 8.1: The results of a large grid of quasar emission-line cloud calculations are shown. The x - y plane shows the logs of the hydrogen density (cm^3) and flux of ionizing photons ($\text{cm}^{-2} \text{s}^{-1}$). The z axis is the predicted line equivalent width.

8.1.2 Creating a new main program

In C++ there must be exactly one main program and it must be called *main*. This routine is within the file `maincl.cpp` in the source downloaded from the web. You need to replace the existing CLOUDY main program with one that you write. The file `maincl.cpp` that is included in the distribution must be deleted so that the program you write will be loaded instead. The remaining routines are then compiled with a command like the following:

```
g++ -O3 -c *.cpp
```

which will create a large number of object files. The new main program will then need to be linked with these object files with a command something like

```
g++ -O3 -o mycloudy.exe newmain.cpp *.o -lm
```

Alternatively, if you are using the Makefile build process and have already built CLOUDY, you can use the library file `libcloudy.a` which contains all the object files with the command

```
g++ -O3 -o mycloudy.exe newmain.cpp -L. -lcloudy -lm
```

The following subsections outline how to write code for this new main program.

8.1.3 The `cddefines.h` and `cddrive.h` header files

The file `cddrive.h` contains definitions of all public routines, the routines that a user would call to drive CLOUDY. That file is the definitive reference for the material contained in this section and is more up to date than this document. Comments within that file explain all routines and their parameters.

The header `cddefines.h` should come before `cddrive.h` since it includes many definitions and includes the standard C++ header files that are needed to drive the code. The first two header files in the new main routine should be the following:

```
#include "cddefines.h"  
#include "cddrive.h"
```

8.1.4 The template for main programs

C++ exceptions are used by CLOUDY. The main program must catch these exceptions. If it does not then the code will crash with an unhandled exception and output files will not be complete. This requires that the main program start with a C++ “try” block and that exception handlers be included within the main program. The adventurous user may enjoy creating their own try block/exception handlers.

A sample template, in the file `template.cpp`, includes the needed code and can be used to create your own programs. It is included in the `programs` directory below the `tsuite` directory in the program download. That version includes a simple call to run the code’s smoke test. You would replace the existing code with your own.

8.1.5 A note on return conditions

Some of the routines return a value to indicate success or failure. I try to follow the C and Unix conventions to indicate success with zero (or *false*) and trouble with a non-zero return (or *true*). This rule is not always followed (it is not followed by the important routine *cdLine*), however, and *cddrive.h* should be consulted to make sure the return conditions are understood.

8.2 Initializing the code

Many variables must be initialized at the beginning of the calculation. Calling routine *cdInit* does this.

```
cdInit();
```

Routine *cdInit* must be called every time a new calculation is to be performed, *before* calling any of the following subroutines, but after the results of any previous calculations have been read. (The results of any previous calculations are lost when *cdInit* is called.)

8.3 Handling input and output

8.3.1 cdTalk—produce output?

CLOUDY normally speaks what's on its mind. This would generate too much output in a large grid. It does have a quiet mode in which nothing at all is printed. This quiet mode is set by the logical argument to subroutine *cdTalk*.

```
#include "cddefines.h"
#include "cddrive.h"
cdInit();
/*set no output at all*/
cdTalk( false )
/*have the code produce the normal printout*/
cdTalk( true )
```

The default is for CLOUDY to produce output. *cdTalk* does not have to be called if this is what you want. It needs to be called with the logical variable *false* if the quiet mode is desired.

8.3.2 cdOutput—sending output to a file

CLOUDY normally writes its standard output on the system's *stdout*. This can be changed to another file by calling the routine *cdOutput*, which has two arguments. The first is the name of the file, and the second the mode with which the file should be opened (this is identical to the second parameter of the *fopen()* routine). Both parameters have default values. The default mode for opening the file is "w", while the default filename is the empty string. Supplying an empty string as the file name means that the output will be directed back to *stdout* again. The output file will be automatically closed on exit of the program. If you call *cdOutput* multiple times with different file names, the file from the previous call will also be closed automatically. The new output file needs to be in the local directory, i.e., writing to a subdirectory or an absolute path is not allowed.

```
#include "cddefines.h"
#include "cddrive.h"

/* open the file output.txt for writing with mode "w" */
/* this will overwrite an existing file */
cdOutput("output.txt");

/* if you want to append to a file, use this instead */
cdOutput("output.txt","a");

/* this will close output.txt and open output2.txt with mode "w" */
cdOutput("output2.txt");

/* if you now want to redirect to stdout again, use this */
/* this will close output2.txt */
cdOutput();
```

8.3.3 cdInput—reading input from a file

CLOUDY normally reads input from the system's `stdin`. This can be changed to another file by calling the routine `cdInput`, which works the same way as the `cdOutput` command described above with the following two exceptions: the default open mode is “r”, and supplying an empty string as the file name redirects input back to `stdin`.

8.3.4 cdRead—entering Commands

Command lines are entered by successive calls to the routine `cdRead`. The argument of `cdRead` is a string containing valid commands. These commands must obey all the rules outlined in Part 1.

In the examples below some commands are directly entered as strings (this works when the string is a constant) while other strings are created by writing variables through *sprintf* (a standard C I/O function) or the C++ container `ostringstream`. C++ I/O has the advantage that you do not have to worry if your buffer is big enough to hold the input line, but otherwise both methods should work equally well. Using either of these methods is necessary when the value of a variable needs to be placed into a string.

```
char chLine[200];/* this string will hold the command lines we will generate*/

/* this example sends the string straight to cdRead */
cdRead( "title a series of constant pressure models" );

/* write variable to a string, then send the string to cdRead */
hden = 5.4;
sprintf( chLine, "hden %5.2f", hden );
cdRead( chLine );

/* this example sends a string that contains double quotes,
 * and so we must "escape" them with backslashes */
cdRead( "save overview \"test.ovr\"" );

/* here we use C++-style I/O as an alternative */
ostringstream oss;
```

```
oss << "coronal " << temp ;
cdRead( oss.str() );

cdRead( "stop zone 1" );
```

You can enter as many input lines as you need. There is no limit other than what the amount of memory on your computer can hold. *cdRead* returns an int that always holds the value *INT_MAX*¹. The return value was ignored in the examples above.

8.4 Executing the code

8.4.1 cdDrive—calling the Code

The calculation is performed when routine *cdDrive* is called. *cdDrive* returns a bool indicating whether the calculation aborted. The value *false* indicates a successful calculation. The following shows an example of its use.

```
if( cdDrive() )
{
    printf("problems!\n");
    cdEXIT(EXIT_FAILURE);
}
```

If problems occurred and the results cannot be trusted then the return value is *true*. This will only be set if the calculation suffered a complete meltdown. Routine *cdNwcns* can be called to find out about any problems.

8.4.2 cdNoExec—checking without Computing

If routine *cdNoExec* is called after *cdInit* but before *cdDrive* then only the initial parts of a calculation will be performed when routine *cdDrive* is called.

```
cdInit();

/*read in commands */
cdRead( . . . );

/*tell it not to execute */
cdNoExec();

/*call the code */
if( cdDrive() )
    cdEXIT(EXIT_FAILURE);
```

When *cdDrive* is called after *cdNoExec* the code will generate the incident continuum, set the initial density, and derive the chemical composition. It will then stop just before the initial search

¹In versions C17 and earlier the return value indicated how many lines could still be entered. Now that the restriction on the number of input lines has been lifted, this return value is no longer needed, but has been retained for backward compatibility.

for the physical conditions in the first zone. All of the initial printout, summarizing properties of the composition and continuum, will be generated. This provides a quick way to check that a large grid of models will be specified correctly without actually fully computing the grid.

8.5 Ending the code

The code must end by calling *cdEXIT*. This routine will close any open output files and do other needed jobs before exiting. The full output may not be produced if this routine is not called. Routine *cdEXIT* takes a single parameter, *EXIT_SUCCESS* or *EXIT_FAILURE*, standard macros that indicate how the program ended.

The routine *cdEXIT* is a pair with *DEBUG_ENTRY*. Any routine that calls *cdEXIT* must also have a call to *DEBUG_ENTRY* statement at the start. The routine *DEBUG_ENTRY* has a single parameter, a string giving the name of the routine (which should be “main()”) in the case of the main program.

8.6 Checking Predictions

This section describes a series of routines that allow predicted quantities to be obtained after the calculation is complete.

8.6.1 cdB21cm—mean magnetic field

The return value is the mean magnetic field weighted by $n(\text{H}^0)dr/T_{\text{spin}}$. This is related to the field measured with 21 cm Zeeman observations. A tangled magnetic field is assumed. A magnetic field is not included by default but can be added with the **magnetic field** command, described in Part 1 of this document.

8.6.2 cdColm—the computed column densities

The predicted column densities of some species can be obtained by calling routine *cdColm*:

```
/* want N(C+2) */
if(cdColm("carb", 3 , &column))
{
    printf(" could not find C+2\n");
}
else
{
    printf("The predicted C+2 column density is %e\n", column );
}
```

The routine returns zero if it found the species, and 1 if it could not. It returns the predicted column density [cm^{-2}] as the third argument. The first argument *chLabel* is a four-character string that must agree with the first four characters (upper or lower case) of the name used to indicate the element in the printout. The second (integer) variable *ion* is the spectroscopic designation of the level of ionization, i.e., 1 indicates the atom C^0 , 3 indicates C^{+2} , etc.

Table 8.1: Special cases and examples, cdColm Column Densities

Excited states		molecules
Label	Level	Label
He1*	He ⁰ 2 ³ S	H2
C+1[2]	C ⁺ $J = 3/2$	H-
C[1]	C ⁰ $J = 0$	H2+
C[2]	C ⁰ $J = 1$	H3+
C[3]	C ⁰ $J = 2$	H2g
C+2[2]	C ²⁺ $J = 0$	H2*
C+2[3]	C ²⁺ $J = 1$	HeH+
C+2[4]	C ²⁺ $J = 2$	CO
O[1]	O ⁰ $J = 2$	OH
O[2]	O ⁰ $J = 1$	H2O
O[3]	O ⁰ $J = 0$	O2
Si+[1]	Si ⁺ $J = 3/2$	SiO
		H-
		C2
		C3
		CN
		CH
		CH ⁺
H2vJ	H ₂ any v, J	H2

The ion stage of 0 indicates a special case, a molecule or an excited level of an atom or ion. The label determines the species in this case. Molecules with names less than 4 characters can be accessed by this route, as well as ions with their chemical designation (e.g. C+ for C⁺). H2 accesses the total H₂ density, H2g and H2* access the ground and excited state densities. If the label is shorter than four characters, padding the string with spaces is optional for backward compatibility².

If the label has at the end a number contained in square brackets, e.g. C+[2], then the column density is printed for the species excitation level with this index. The index of the level is as given in the corresponding data file. So C+[2] is the level with index 2 of the C⁺ ion. Certain special cases can also be accessed if the fourth character is a *, in particular Si2* and He1* as documented in Table 8.1.

A large and complex model of the H₂ molecule is computed when the **atom H2** command is included. It is possible to obtain column densities in any v, J level of H₂ by calling routine *cdH2_colden*.

8.6.3 cdCooling_last—last zone's cooling

The return value is the total cooling rate (erg cm⁻³ s⁻¹) for the last computed zone.

²In version C13 and before, the label string had to be exactly 4 characters long at all times.

8.6.4 *cdDepth_depth*—the depth structure of the cloud

This routine returns a vector giving the zone depths (in cm) of the previous iteration. The code uses adaptive logic to control the radial zoning of the model. Neither the number of depth points nor their structure is known in advance. This routine is called with a double precision vector with enough space to hold the structure. The number of depth points is determined by calling *cdnZone* and space must be allocated by the calling routine. Each element of the vector is the depth from the illuminated face to the center of zone *n*.

8.6.5 *cdEDEN_last*—electron density of last zone

This returns the electron density (cm^{-3}) of the last zone.

8.6.6 *cdEmis*—emissivity of lines

cdEmis has the same arguments as *cdLine* but returns the local emissivity ($\text{erg cm}^{-3} \text{s}^{-1}$ for unit filling factor) of the line for the last computed zone. The return value is the index of the line within the line stack if it was found, and the negative of the number of lines in the stack if the line could not be found.

8.6.7 *cdGetLineList*—sets of emission lines

The routine *cdGetLineList* provides a way to automatically access a list of emission lines.

First enter a list of emission lines into a file. The format is described in Sect. 16.68.7 of Part 1 of this document. A set of such files is included in the data directory of the distribution files. They have names *LineList*.dat*. You can use these as examples to create your own files.

The first argument to routine *cdGetLineList* is the name of the file containing the line list. If a null string is passed ("") then *LineList_BLR.dat* is used.

cdInit must be called before *cdGetLineList* is called. Next *cdGetLineList* is called, and finally, the actual grid of calculations begins. The predicted intensities of a set of lines are then extracted by calling *cdLine*.

The second and third parameters are a pair of vectors that are defined by the calling program. When the routine *cdGetLineList* is called it uses these vectors to store the labels and wavelengths. The function returns the number of lines in the list. If problems occurred then -1 is returned.

The following shows an example of getting the lines from *LineList_NLR.dat*, executing the code, and then obtaining the predicted intensities of all lines listed in *LineList_NLR.dat* by calling *cdLine*.

```
#include "cddefines.h"
#include "cddrive.h"
#include "lines.h"
/* define variables */
exit_type exit_status = EXIT_SUCCESS;
vector<LineID> lineids;
/* initialize the code */
cdInit();
/* get list of lines from a line list included in the distribution */
```

```

if( (nLines=cdGetLineList("LineList_NLR.dat",lineids)) < 0 )
{
    /* this is the error exit - could not obtain the lines */
    cdEXIT(EXIT_FAILURE);
}
/* missing commands here, then call the code */
- - - - - missing code
if( cdDrive() )
    exit_status = EXIT_FAILURE;
- - - - - missing commands go here
/* now print the predicted emission line intensities */
for( long n=0; n < nLines; ++n )
{
    if( cdLine( lineids[n], &relative, &absolute ) < 0 )
    {
        fprintf(stderr,"did not find %s %g\n",lineids[n].chLabel.c_str(),lineids[n].wave);
    }
    print("%.3e\n", relative);
}
cdEXIT(exit_status);

```

8.6.8 cdH2_colden—state-specific column densities of H₂

This returns the column density of any level in the X ground electronic state of H₂. This command only works when the large H₂ molecule is included with the **atom H2** command. It has two integer arguments, the vibration and rotation quantum numbers of a level in X. If both are zero or greater the routine returns the column density in that level. If the vibration quantum number is negative then a summed column density is turned. If $v < 0$ and $J = 0$ it returns the total H₂ column density, if $J = 1$ it returns the ortho column density, and if $J = 2$ the para column density. If the indices do not make sense the routine prints a message and returns -1 .

Here are some examples:

```

/* total H2 column density */
total = cdH2_colden( -1 , 0 );
/* ortho column density */
ortho = cdH2_colden( -1 , 1 );
/* para column density */
para = cdH2_colden( -1 , 2 );
/* column density in 0, 0 */
total00 = cdH2_colden( 0 , 0 );

```

8.6.9 cdH2_Line—an H₂ emission line intensity

More than half a million H₂ lines are predicted and there will be instances where two H₂ lines have nearly the same wavelength. Identification of a particular transition within the list of lines can be ambiguous. This command finds the intensity and luminosity of a transition by specifying its upper and lower n, v, J levels. The first six arguments give the n, v, J indices of the upper and lower levels in that order. The last two variables are double pointers that return the intensity and luminosity of the transition. The function returns 1 if it finds the line and 0 if it did not. (This

behavior follows that of *cdLine* rather than the standard C++ conventions on function return values.) Currently this only works for the ground electronic state.

Here is an example:

```
double xInten , xLumin;
/* the 1-0 S(1) at 2.121 microns */
if( cdH2_Lines( 0,1,3 , 0,0,1 , &xInten , &xLumin ) == 0 )
{
    printf("could not find line.\n");
}
```

8.6.10 *cdHeating_last*—last zone's heating

The total heating rate ($\text{erg cm}^{-3} \text{ s}^{-1}$) for the last computed zone is returned.

8.6.11 *cdIonFrac*—the computed ionization fractions

The predicted ionization fractions,³ averaged over radius, area, or volume, can be accessed by calling the subroutine *cdIonFrac*. The average over radius is defined as

$$\left\langle \frac{n(S^{+n})}{n(S_{\text{gas}})} \right\rangle = \frac{\int n(S^{+n}) f(l) dl}{\int n(S_{\text{gas}}) f(l) dl} \quad (8.1)$$

where $n(S_{\text{gas}})$ is the total gas phase density of the element. The average over area is defined as

$$\left\langle \frac{n(S^{+n})}{n(S_{\text{gas}})} \right\rangle = \frac{\int n(S^{+n}) f(r) r dr}{\int n(S_{\text{gas}}) f(r) r dr}. \quad (8.2)$$

The average over volume is defined as

$$\left\langle \frac{n(S^{+n})}{n(S_{\text{gas}})} \right\rangle = \frac{\int n(S^{+n}) f(r) r^2 dr}{\int n(S_{\text{gas}}) f(r) r^2 dr}. \quad (8.3)$$

Two sample calls to the routine follow:

```
/* false below means to not include electrons in the mean */
if( cdIonFrac("carb", 2, &frac, "radius", false) )
{
    cdEXIT(EXIT_FAILURE);
}
printf("The predicted ionization fraction over radius is %g\n", frac);
/* true below means to include electrons in the mean */
if( cdIonFrac("carb", 2, &frac, "radius", true) )
{
    cdEXIT(EXIT_FAILURE);
}
printf("Ionization fraction wrt radius end elec den is %g\n", frac);
```

³Before version 96 the ionization fractions only included atoms and ions. They now also include molecules. The sum of the atomic and ionic fractions will not add up to unity if a significant fraction of the element is in molecules.

The first argument is a four-character identifier that must agree with the first four characters (upper or lower case) used to indicate the element in the printout. The second integer argument is the spectroscopic designation of the level of ionization, i.e., 1 indicates C^0 , 3 indicates the second ion C^{+2} , etc. The third argument returns the predicted ionization fraction S^{+n}/S_{gas} . The 4th argument is a six-character variable (plus end of string sentinel) which must be either “*radius*”, “*area*”, or “*volume*” (either upper or lower case). This string determines whether the ionization fraction returned is weighted with respect to radius, area, or volume. These would be appropriate to compare to pencil beam observations, integrated long slit observations, or observations of the whole nebula, respectively. The last argument determines whether (*true*) or not (*false*) the ionization fraction is also weighted with respect to the electron density. The function returns zero if the ion was found and non-zero if an error occurred.

An ionization stage of zero will request the fraction of an element within a molecule. If the element name is “H2”, then the fraction of hydrogen in H_2 , $2n(H_2)/n(H_{tot})$, will be returned. Currently only H_2 is implemented. In this case, padding the string “H2” with spaces is optional for backward compatibility⁴.

8.6.12 cdLine—emission-line intensities

This finds the intensity or luminosity of any line. The label and wavelength of the line are specified and the routine returns the relative intensity and the absolute intensity or luminosity. The following is an example.

```
#include "cddefines.h"
#include "cddrive.h"
double relint, absint;
long nType = 0;

if( cdLine( "H 1", 4861.33, &relint, &absint, nType ) < 0 )
    printf("did not find this line\n");
```

The first argument in the call is the line label, the string (upper or lower case) used by the code to identify the line in the main emission-line printout. The second variable gives the wavelength of the line in Angstroms. Both of these must exactly match the label and wavelength used by CLOUDY to identify the line (see the chapter *Lines* for a full description). The third variable (*relint* in the above example) is a double-precision pointer to the relative intensity of the line (relative to the normalization line, usually $H\beta$, and reset with the **normalize** command). The intensity ($\text{erg cm}^{-2} \text{s}^{-1}$) or luminosity (erg s^{-1}) of the line is returned as the fourth double-precision pointer (*absint* in the above example). If the intensity of the line is zero or the line was not found then this variable will be set to 0.

The last (optional) parameter indicates which type of line prediction to return. The integer types are 0 intrinsic, 1 emergent, 2 intrinsic cumulative, 3 emergent cumulative intensities.

The intensities returned when the last parameter is missing or it is zero are those printed with the heading *Intrinsic Intensities*. This does not include the effects of possible reflection off a background molecular cloud or of absorption from outside the emission-line region. If the last parameter is 1 then emergent intensities are reported. The values 2 and 3 are the equivalent quantities for the cumulative intensities in a time dependent model.

⁴In version C13 and before, the label string had to be exactly 4 characters long at all times.

Sometimes the line label and wavelength are not enough to uniquely specify a line. For this case an alternate calling sequence can be used. The line can be disambiguated by specifying either the indices of the lower and upper level, or the energy of the lower level (see Section 2.5.3 in Hazy 1 for further details). When using *cdLine*, this can be done as follows:

```
#include "cddefines.h"
#include "cddrive.h"
#include "lines.h"
double relint, absint;
long nType = 0;

// example using lower and upper level index
if( cdLine( LineID("H 1", 46524.7, 11, 23), &relint, &absint, nType ) < 0 )
    printf("did not find this line\n");
// same line, but using lower level energy (in cm^-1) instead
if( cdLine( LineID("H 1", 46524.7, 105291.6), &relint, &absint, nType ) < 0 )
    printf("did not find this line\n");
```

If *cdLine* finds the line it returns the index of the line within the stack of emission lines. So a positive return value indicates success. It returns the negative of the total number of lines in the stack if the line is not found. This may occur if the line wavelength or label was mistyped. This is an exception to the C++ function return convention in which a normal return is zero and an abnormal return is non-zero. A positive value indicates a successful return.

There is a special version, *cdLine_ip*, which takes the line index as the first argument and return the relative and absolute intensities as the second and third quantities. The line index is not a constant for a given version of the code. It depends (amongst others) on the number of elements that are included, the sizes of the iso-sequence model atoms, and whether other models like H₂ are included.

8.6.13 *cdnZone*—how many zones in the last iteration?

The routine returns the number of zones in the previous iteration.

8.6.14 *cdPressure_depth*—pressure structure of the last iteration

The pressure as a function of depth, for the last iteration, is obtained by calling routine *cdPressure_depth*. This routine has three arguments, pointers to vectors giving the total pressure, the gas pressure, and the line radiation pressure. All are double precision vectors and the calling routine must have allocated space for these before calling the routine. The total number of elements needed for each vector is the number of zones in the last iteration and is obtained by calling routine *cdnZone*.

8.6.15 *cdPressure_last*—pressure of the last zone

The pressure for the last zone is obtained by calling routine *cdPressure_last*. This routine has three arguments, pointers to the total pressure, the gas pressure, and the line radiation pressure. All are double precision variables. The total pressure includes all contributors to the pressure and may include magnetic, radiation, and turbulent pressure in addition to thermal pressure.

8.6.16 cdTemp—the computed mean temperature

There are two versions of the *cdTemp* function. Both return the mean electron temperature weighted with respect to some species.

cdTemp(element, stage, &Temp, weight)

This version supports all ions, the “H2” molecule, and a few special labels.

The first parameter is a four character null-terminated string giving the first four letters (upper or lower case) of the name of an element as spelled by the code. The second parameter is the ionization stage, with 1 for the atom, 2 the first ion, etc. The third parameter will be the computed mean temperature. The last parameter is a six-character null-terminated string, either “radius”, “area”, or “volume”, that says whether the temperature should be weighted with respect to radius, area, or volume. These would be appropriate to compare to pencil beam observations, integrated long slit observations, or observations of the whole nebula, respectively. The mean temperature weighted by ion $+n$ of element S over radius is defined as

$$\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(l) dl}{\int n(S^{+n}) f(l) dl} \quad [\text{K}], \quad (8.4)$$

the average over area is

$$\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(r) r dr}{\int n(S^{+n}) f(r) r dr} \quad [\text{K}], \quad (8.5)$$

and the average over volume is

$$\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(r) r^2 dr}{\int n(S^{+n}) f(r) r^2 dr} \quad [\text{K}]. \quad (8.6)$$

The routine returns 0 if it finds the species, and 1 if it could not find the species. The following is an example of a call:

```
if( cdTemp("carb", 2, &temp, "radius") )
{
    cdEXIT(EXIT_FAILURE);
}
printf("The mean C+ temperature is %g\n", temp);
```

An ionization stage of zero requests one of the following special temperatures. All these can be weighted by radius, area, or volume.

21 cm-related temperatures: The routine will return one of three temperatures related to 21 cm observations. The label “**21cm**” will return the mean of $n(\text{H}^0)/T_{kin}$, the harmonic mean gas kinetic temperature weighted with respect to the atomic hydrogen density. The label “**spin**” will return the mean weighted by $n(\text{H}^0)/T_{spin}$, the harmonic mean of the 21 cm spin temperature weighted with respect to the atomic hydrogen density. Finally the label “**opti**” returns the temperature derived from the ratio of $L\alpha$ to 21 cm optical depths (see AGN3 section 5.5).

Molecular hydrogen: The label “H2” and an ionization stage of zero will return the mean temperature weighted with respect to the H₂ density.

Simple mean temperature: If the label is an empty string, as in “”, and the ionization stage is zero, the routine will return the mean temperature, but not weighted by any species. If the label is “TeNe” then the routine will return the mean temperature weighted by the electron density. If the label is shorter than four characters, padding the string with spaces is optional for backward compatibility⁵.

cdTerm(species, &Temp, weight)

This version supports all ions, all molecules, and a few special labels.

The first parameter is the string of the ionic or molecular species. The second parameter will be the computed mean temperature. The last parameter is a six-character null-terminated string, either “radius”, “area”, or “volume”, that says whether the temperature should be weighted with respect to radius, area, or volume. These would be appropriate to compare to pencil beam observations, integrated long slit observations, or observations of the whole nebula, respectively. The mean temperature weighted by ion $+n$ of element S over radius is defined as

$$\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(l) dl}{\int n(S^{+n}) f(l) dl} \quad [\text{K}], \quad (8.7)$$

the average over area is

$$\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(r) r dr}{\int n(S^{+n}) f(r) r dr} \quad [\text{K}], \quad (8.8)$$

and the average over volume is

$$\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(r) r^2 dr}{\int n(S^{+n}) f(r) r^2 dr} \quad [\text{K}]. \quad (8.9)$$

The routine returns 0 if it finds the species, and 1 if it could not find the species. The following is an example of a call:

```
if( cdTemp("C+", &temp, "radius") )
{
    cdEXIT(EXIT_FAILURE);
}
printf("The mean C+ temperature is %g\n", temp);
```

The following special temperatures are supported. All these can be weighted by radius, area, or volume.

21 cm-related temperatures: The routine will return one of three temperatures related to 21 cm observations. The label “21cm” will return the mean of $n(\text{H}^0)/T_{kin}$, the harmonic mean gas kinetic temperature weighted with respect to the atomic hydrogen density. The label “spin” will return the mean weighted by $n(\text{H}^0)/T_{spin}$, the harmonic mean of the 21 cm spin temperature weighted with respect to the atomic hydrogen density. Finally the label “opti” returns the temperature derived from the ratio of $L\alpha$ to 21 cm optical depths (see AGN3 section 5.5).

⁵In version C13 and before, the label string had to be exactly 4 characters long at all times.

Simple mean temperature: If the label is an empty string, as in "", the routine will return the mean temperature, but not weighted by any species. If the label is "TeNe" then the routine will return the mean temperature weighted by the electron density.

8.6.17 `cdTemp_last`—the temperature of the last zone

The kinetic temperature of the last zone is obtained by calling the function *cdLastTemp*. The function has no arguments and its return value is the temperature.

8.6.18 `cdTimescales`—several timescales.

This routine has three arguments, pointers to doubles that return the timescales [s] for several processes. These are the thermal timescale, the hydrogen recombination timescale, and the H₂ formation timescale.

8.7 Other information

8.7.1 `cdDate(cdString)`

The date when the current version of the code was released will be placed as a null-terminated string. The string is passed as an argument and the calling program must have allocated enough room for the string.

8.7.2 `cdVersion(cdString)`

The code's version number will be placed as a null-terminated string into the string passed as an argument. The version number is a string rather than a float since it can end with a letter of the alphabet. The calling program must allocate enough space for the string.

8.7.3 `double cdExecTime()`

This returns the time that has elapsed since the previous call to *cdInit*.

8.8 Printing comments

CLOUDY is designed to be autonomous and self aware. It constantly monitors itself to make sure that it is doing the physics correctly. After the calculation is complete, but before the emission lines are printed, it generates a series of statements that indicate warnings, cautions, comments, and surprises. These should be examined to confirm that the calculation is likely to be valid. A series of routines allows the driving code to determine whether these comments were generated, what type they were, and to print them into an arbitrary open file.

8.8.1 Were comments generated?

Routine *cdNwcns* will return the number of warnings, cautions, surprises, notes, and temperature and pressure failures:

```
cdNwcns( &lgAbort , &nw , &nc , &nn , &ns , &nte , &npe , &none, &neden )
```

where the first variable is a *bool* flag indicating whether the calculation aborted, *nw* is the number of warnings generated (if this number is non-zero, then the calculation has serious problems), *nc* is the number of cautions generated (these are less severe than warnings, but are still a cause of concern), and *nn* and *ns* are the number of notes and surprises. The next two arguments are the number of temperature and pressure failures. The last two are the number of ionization and electron density failures. There should not be any failures in a successful calculation.

If either of the first two variables are non-zero then the code ran into serious problems. An abort is far more serious than a warning since it indicates catastrophic failure. I would appreciate learning about these. Please post details on the code's discussion board.

8.8.2 Printing the comments.

A series of comments normally appear after the last zone. These may be printed into any file by calling the series of subroutines described here. In all cases the routines take as an argument a file handle which must point to a file that has already been opened for writing.

```
/* output the comments into a file
 * first define the file handle, then open the file for writing */
FILE *ioOUT;
if( (ioOUT = fopen( "comments.txt", "w" ) ) == NULL )
{
    printf("error creating comments.txt file\n");
    cdEXIT(EXIT_FAILURE);
}
--- missing code to do calculation ---
/*print the reason the calculation stopped, and geometry*/
cdReasonGeo(ioOUT);
/*print the warnings*/
cdWarnings(ioOUT);
/*next print the cautions*/
cdCautions(ioOUT);
/*now print any surprising results*/
cdSurprises(ioOUT);
/*now print the notes*/
cdNotes(ioOUT);
fclose(ioOUT);
```

cdReasonGeo(FILE *io) It is very important to understand why the calculation stopped. The first two lines after the last zone results give the reason the calculation stopped and the type of geometry. This information will be printed into the file whose handle is the argument.

cdWarnings(FILE *io) All warnings (denoted by “W-”) will be printed.

cdCautions(FILE *io) All cautions (denoted by a “C-”) will be printed.

cdSurprises(FILE *io) All surprises (denoted by a “!”) are printed.

cdNotes(FILE *io) The notes concerning the calculation will be printed.

8.8.3 cdErrors(FILE *io)—printing a summary of any problems

Routine *cdErrors(FILE *io)* will generate a summary of any problems that happened during a calculation. The argument is a pointer to the output file where the summary will be placed. The calling program must have already opened the file for writing. If problems occurred in the calculation, such as temperature or pressure failures, warnings, or cautions, will be printed along with the calculation’s title.

8.8.4 cdPrintCommands(FILE *io)—print the command stack

The entire series of input commands will be written into the file. The single argument is a file handle that points to a previously opened file. The commands are preceded and followed by lines that begin with “c =====” to easily identify their start and end.

8.8.5 setbuf or the no buffering command

Programs produce output by writing into a buffer. They only place information on the disk once the buffer is full. If a C++ program crashes before this buffer is “flushed” the information within the buffer will be lost. This poses a problem if the printout generated just before the crash is needed for debugging. The C++ io library provides a routine, *setbuf*, that can turn file buffering off. The following sequence would open a file and turn buffering off:

```
ioDATA = open_data("test.out", "w", AS_LOCAL_ONLY);
/* turn off buffering so we see results as then happen */
setbuf( ioDATA , NULL );
```

Note that the call to *setbuf* *must* come immediately after the call to *open_data* before any output is written. The **no buffering** command, described in Part 1 of this document, will do the same thing. Note that turning off buffering will make the code run far more slowly.

8.9 Example Call as a Subroutine

The file `template.cpp` shown below contains a skeleton program showing how you can call Cloudy as a subroutine. You can find the program in the directory `tsuite/programs`. Use this as a starting point to write your own program. The area where you can insert your own code is clearly indicated in the template.

```
/* This file is part of Cloudy and is copyright (C)1978-2019 by Gary J. Ferland and
 * others. For conditions of distribution and use see copyright notice in license.txt */
/* Template main program for calling Cloudy as a subroutine
 * Routine returns 0 if model is ok, and 1 if problems occurred. */
#include "cddefines.h"
#include "cddrive.h"

int main( int argc, char *argv[] )
{
    exit_type exit_status = ES_SUCCESS;
```

```

DEBUG_ENTRY( "main()" ); // do not remove this!

try {
    // =====
    // START ENTERING YOUR CODE AFTER THIS LINE
    // inside this try block you can enter your code to call Cloudy as a subroutine
    // replace the code between here and the next ===== line with your own program

    // the code always needs to be initialized first
    cdInit();

    // to write output to a file, you MUST open it with open_data()
    // no need to check for a NULL pointer on return as open_data() will have done that already
    FILE* io = open_data("sample.out", "w");

    // you can call Cloudy in a loop if you want...
    for( int i=0; i < 1; ++i )
    {
        // the code always needs to be initialized first
        cdInit();
        // replace this with a series of calls to cdRead to define the input script
        // this particular command line exercises the smoke test
        cdRead( "test" );
        // this calls Cloudy to execute the input script you defined above
        if( cdDrive() )
            exit_status = ES_FAILURE;
    }

    cdEXIT(exit_status); // always exit with cdEXIT, this assures files are properly closed.
    // =====
    // THIS IS THE END OF THE PROGRAM YOU WROTE
    // this ends the try block - your code calling Cloudy ends above this line
}
// here we catch all the possible exceptions that the code can throw, do not remove this!

return exit_status;
}

```

8.10 Computing Grids of Calculations

Today I usually use the code to compute results, extract information, and save desired quantities. The following example illustrates producing a series of models with increasing gas temperature and density. The program calculates the line strength of various diagnostic [O III] lines normalized to [O III] $\lambda 5007$ and writes these to a file. This example is the program `vary_nete.cpp`, which you can find in the directory `tsuite/programs/vary_nete`.

This example only saves results for a few lines. Often a large number of lines are needed. A call to `cdLineList` provides an easy way to obtain large numbers of lines whose labels are stored in a file.

```

/* This file is part of Cloudy and is copyright (C)1978-2019 by Gary J. Ferland and
 * others. For conditions of distribution and use see copyright notice in license.txt */
/*main program that calls cloudy when used as a stand-alone program */
#include "cddefines.h"
#include "cddrive.h"

/*int main( int argc, char *argv[] )*/
int main( void )
{
    exit_type exit_status = ES_SUCCESS;

    DEBUG_ENTRY( "main()" );

Chapter 9

THE EMISSION LINES

9.1 Overview

The following sections outline the emission lines predicted by CLOUDY. Before version 90 of the code all lines were listed in the sub-section immediately following this section. The code is being modified to bring all lines into a common line class, as the code moves to C++ and objects. This chapter will remain incomplete until this work is finished.

9.2 The main emission-line printout

The main emission line printout was briefly described in the Chapter *OUTPUT*. This section goes into more detail.

Output organization. The printed list is sorted into four large groups of columns, with each large column sub-divided into four smaller sub-columns. The first sub-column is either the spectroscopic designation of the ion producing the line or an indication of how the line is formed. The second sub-column is the line wavelength, with a 0 to indicate a continuum. The third sub-column is the log of the power in the line, in the units given in the header (erg s^{-1} into either $4\pi \text{ sr}$ or cm^{-2}). The last sub-column is the intensity of the line relative to the reference line, usually $H\beta$, unless this is reset with the **normalize** command.

These lines can be printed as a single large column, and can be sorted by wavelength or intensity. These options are controlled by the **print line** command described in Part I of this document.

9.2.1 Intrinsic and emergent line intensities

See Section [2.10](#).

9.2.2 Units of Line wavelengths

These can be given in various units. Numbers ending in “A” are wavelengths in Angstroms (\AA). For instance, $H\beta$ is given by “H 1 4861A”. Wavelengths in microns are indicated by “m”, an example, the strong [O III] IR line, is “O 3 51.80m”.

Continua are usually indicated by a wavelength of zero.

9.2.3 Air vs vacuum wavelengths

The emission line wavelengths follow the convention that vacuum wavelengths are used for $\lambda < 2000\text{\AA}$ and STP air wavelengths are used for $\lambda \geq 2000\text{\AA}$. The **print line vacuum** command tells the code use vacuum wavelengths throughout. **Save continuum** output is always reported in vacuum wavelengths to avoid a discontinuity at 2000\AA .

9.2.4 Blocks of lines in main output

Lines are organized by common origin with a comment, ending in a series of periods "...", beginning the section. As an example, the first commented block of lines begins with "general properties...". The following subsections give overviews of the lines.

9.2.5 General properties...

This mainly summarizes heating and cooling agents for the model.

H 1 4861 and H 1 1216, are the total intensities of $H\beta$ and $L\alpha$, as predicted by the multi-level H atom. These intensities are the results of calculations that include all collisional, radiative, and optical depth effects.

Inci The total energy in the incident continuum. This entry will not be included if the **aperture** command is in effect.

TotH and TotC give the total heating and cooling. These will be nearly equal in equilibrium.

BFH1 and BFHx are the heating due to photoionization of ground state and excited state hydrogen respectively.

He1i, 3He1 , heating due to ground state He and the triplets.

BFHe and TotM are the heating due to helium and metal photoionization.

Pair heating due to pair production.

ComH , ComC , Compton heating, cooling.

CT H CT C charge transfer heating and cooling.

extH extC "extra" heating or cooling added to model.

e-e+ 511 The positron line.

Expn , expansion, or adiabatic, cooling

H FB , H radiative recombination cooling

HFBC, HFBC , hydrogen net free-bound cooling and heating

Iind , cooling due to induced recombination of hydrogen

3He2 , cooling due to induced recombination of fully ionized helium

Cygn , cyclotron cooling

9.2.6 Continua...

These give intensities of various continua. These are either the total integrated continuum or the product νF_ν at certain energies.

Continuum bands

The file `continuum_bands.ini` in the data directory specifies a set of wavelength bands. The code will integrate over these bands to find the total radiated luminosity and enter this into the main emission-line stack. Currently this is a simple sum of the energy emitted between the upper and lower bounds of the band, and does not take into account the transmission function of particular instruments. The `continuum_bands.ini` file can be edited to change the number of bands or their detailed properties. Table 9.1 lists the bands in the file at the time of this writing. The first and second columns give the label and wavelength as they appear in the printout. The last column gives the wavelength range for the integration. These entries will not be included if the **aperture** command is in effect. Please consult the file to see its current contents and feel free to add your own bands.

Other continua

Bac 3646 residual flux at head of Balmer continuum, νF_ν . This entry will not be included if the **aperture** command is in effect.

cout 3646 cref 3646 , outward, reflected continuum at peak of Balmer Jump. These entries will not be included if the **aperture** command is in effect.

thin 3646 , residual flux at head of Balmer continuum, optically thin limit. This entry will not be included if the **aperture** command is in effect.

Inci 4860, Inci 1215 , incident continua near $H\alpha$ and $L\alpha$. These entries will not be included if the **aperture** command is in effect.

Ba C 0 , integrated Balmer continuum

PA C 0 , integrated Paschen continuum

HeFF 0 , He brems emission

HeFB 0 , He recombination cooling

MeFB 0 , heavy element recombination cooling

MeFF 0 , metal brems emission

Table 9.1: Default continuum bands

Label	Wavelength	Wavelength Range
FIR	83.00m	40.00m – 500.0m
TIR	1800m	500.0m – 3100m
NIRa	2.850m	7000A – 40.00m
NIRb	3.000m	10000A – 5.000m
MIRa	15.00m	5.000m – 25.00m
MIRb	22.50m	5.000m – 40.00m
NMIR	21.75m	7000A – 40.00m
TFIR	611.2m	122.5m – 1100m
TALL	10000A	0.010A – 10000m
F12	12.00m	8.500m – 15.00m
F25	25.00m	19.00m – 30.00m
F60	60.00m	40.00m – 80.00m
F100	100.0m	83.00m – 120.0m
MIPS	24.00m	20.80m – 26.10m
MIPS	70.00m	61.00m – 80.00m
MIPS	160.0m	140.0m – 174.0m
IRAC	3.600m	3.160m – 3.920m
IRAC	4.500m	4.000m – 5.020m
IRAC	5.800m	5.000m – 6.400m
IRAC	8.000m	6.500m – 9.300m
SPR1	250.0m	212.0m – 288.0m
SPR2	350.0m	297.0m – 405.0m
SPR3	500.0m	414.0m – 600.0m
PAC1	70.00m	60.00m – 82.00m
PAC2	100.0m	84.00m – 122.0m
PAC3	160.0m	130.0m – 198.0m
PAH	3.300m	3.250m – 3.350m
PAHC	3.230m	3.200m – 3.250m
PAHC	3.370m	3.350m – 3.400m
PAH	6.200m	5.900m – 6.400m
PAHC	5.650m	5.400m – 5.900m
PAH	7.900m	7.400m – 8.400m
PAHC	6.900m	6.400m – 7.400m
PAH	11.30m	11.10m – 11.50m
PAHC	10.90m	10.70m – 11.10m
PAH	11.80m	11.60m – 12.30m
PAHC	12.65m	12.30m – 13.00m
PAH	13.30m	12.90m – 13.70m
PAHC	14.10m	13.70m – 14.50m
Bcon	3640A	911.6A – 3646A
Pcon	5000A	3646A – 8204A

ToFF 0 , total brems emission

FF x , part of H brems, in x-ray beyond 0.5KeV

eeff , electron - electron brems

nFnu 122m, **nInu 122m**, **InwT 122m**, **InwC 122m**, a large list of continua at selected wavelengths will be printed. These entries will not be included if the **aperture** command is in effect. The first is the sum of various continua at the wavelength, given as νF_ν (see the **set nFnu** command in Part 1 for a discussion of what is included in the **nFnu** entry). **nInu** is the transmitted and reflected incident continuum. **InwT** is the total reflected continuum. **InwC** is the reflected incident continuum.

9.2.7 Molecules...

H2dC , is the cooling due to collisional dissociation of H₂.

H2dH , heating by H₂ dissociation by Lyman continuum

H2vH , heating by coll deexcit of vib-excited H₂

H2vC , cooling by coll deexcit of vib-excited H₂

H2 v , line emission by vib-excited H₂

H-FB and H-FF are the free-bound and free-free continua of the H- ion.

H-CT 6563 , H-alpha produce by H- mutual neutralization

H- H 0, H- heating

H-Hc 0, H- heating

H2+ and **HEH+** are the cooling due to formation of H₂⁺ and HeH⁺.

Codh , carbon monoxide photodissociation heating

CO C 12 , C12O16 cooling

CO C 13 , C13O16 cooling

9.2.8 Species Bands...

Bands in which the emission of a certain species is accumulated are reported in the section of block of lines on the main output headlined with “bands...”. User-specified bands may be provided with the **save species bands** command, described in Hazy 1, Section 16.86.1. By default, the Fe II bands defined in `data/FeIIbands.ini`, if iron is enabled in the model, even if not specified with such a command.

Note that these bands are more fully explained in the output of the command **save line labels**, see Hazy 1, Section 16.68.6.

9.2.9 Grains...

Information in this block concerns emission, absorption, heating, and cooling by any grains included in the calculation.

GrGH , gas heating by grain photoionization

GrTH , gas heating by thermionic emissions of grains

GrGC , gas cooling by collisions with grains

GraT , This is the total grain heating by all sources, lines, collisions, incident continuum. If the grain emission is optically thin limit then this is equal to the total intensity in grain emission.

GraI , grain heating by incident continuum

GraL 1216 , grain heating due to destruction of $L\alpha$

GraC , grain heating due to collisions with gas

GraD , grain heating due to diffuse fields, may also have grain emission

Grain emission is included in the predicted total emitted continuum. A machine readable form of the continuum can be produced with the **save continuum** command, also described in Part I of this document.

9.2.10 H-like iso-seq...

This block includes all hydrogen-like isoelectronic species. The **atom H-like** command, described in Part 1 of this document, adjusts properties of this sequence.

HFFc 0 , net free-free cooling, nearly cancels with cooling in lte

HFFh 0 , net free-free heating, nearly cancels with cooling in lte

H FF 0 , H brems (free-free) cooling

FF H 0 , total free-free heating

Clin 912 , total collisional cooling due to all hydrogen lines

Hlin 912 , total collisional heating due to all hydrogen lines

Cool 1216 , collisionally excited La cooling

Heat 1216 , collisionally de-excited La heating

Crst 960 , cooling due to n_i^2 Lyman lines

Hrst 960 , heating due to n_i^2 Lyman lines

Crst 4861 , cooling due to n_L3 Balmer lines

Hrst 4861 , heating due to n_L3 Balmer lines

Crst 0 , cooling due to higher Paschen lines

Hrst 0 , heating due to higher Paschen lines

LA X 1216 , $L\alpha$ contribution from suprathermal secondaries from ground

Ind2 1216 , $L\alpha$ produced by induced two photon

Pump 4861 , $H\beta$ produced by continuum pumping in optically thin ld limit

CION 0 , net col ionz-3 body heat collision ionization cooling of hydrogen

3bHt 0 , heating due to 3-body recombination

Strk 1216 , Stark broadening component of line

Dest 1216 , part of line destroyed by background opacities

Fe 2 1216 , part of $L\alpha$ absorbed by Fe II

Q(H) 4861 is the intensity of $H\beta$ predicted from the total number of ionizing photons, $Q(H^0)$, assuming that each hydrogen-ionizing photon produces one hydrogen atom recombination. This entry will not be included if the **aperture** command is in effect.

Q(H) 1216 indicates the $L\alpha$ intensity produced if each hydrogen ionizing photon results in one $L\alpha$ photon in the high density limit (i.e., no two-photon emission). This entry will not be included if the **aperture** command is in effect.

CaBo 4861 These are the “old” case B predictions, as printed in versions 90 and before of the code.

Ca B 6563A The entries starting with “Ca B” are the Case B intensities computed from the actual model ionization and temperature structure, but assuming that $H\beta$ emits with its Case B emissivity.

Next the predicted intensities of all lines of the hydrogenic iso-electronic sequence are given. The lines have labels that identify the species and stage of ionization, such as “H 1”, “He 2”, “Li 3”, “C 6”, etc. The entries with a wavelength of zero are the total intensities of the $2s - 1s$ two-photon emission.

9.2.11 He iso-sequence...

Atoms and ions of the helium-like iso-electronic sequence are treated as multi-level atoms. All species and stages of ionization are specified by labels like “He 1”, “Li 2”, “C 5”, etc. A wavelength of zero indicates the two-photon continuum. The 2^3P term is resolved into three levels. Emission of each line of the $2^3S - 2^3P$ and $1^1S - 2^3P$ multiplets is predicted along with the sum of the multiplets with label “TOTL”. The **atom He-like** command, described in Part 1 of this document, adjusts properties of this sequence. Further details are given in [Bauman et al. \(2005\)](#), [Porter et al. \(2005\)](#), and [Porter and Ferland \(2007\)](#).

9.2.12 Recombination...

These are a set of heavy-element recombination lines that are predicted in the low-density limit assuming that the transitions are optically thin. This consists of all recombination lines of C, N., and O, with coefficients taken from [Nussbaumer and Storey \(1984\)](#) and [Pequignot et al. \(1991\)](#).

These predictions are for optically thin pure recombination. These should be accurate for planetary nebulae and H II regions. They will not be accurate for dense environments where optical depths and collisional effects come into play. These are only included in the output if the electron density is less than 10^8 cm^{-3} , a rough upper limit to the range of validity in the original calculations of the coefficients.

There are several instances where more than one line of an ion will have the same wavelength due to the integer Angstrom format used for wavelengths. The worst case is O V 4953, where three lines of the same multiplet have the same wavelength.

9.2.13 Level 2 lines...

These are resonance lines that use Opacity Project wavelengths, which are generally accurate to about 10%. These lines have g-bar collision strengths, which are not very accurate at all.

9.3 The transferred lines

9.3.1 Save line data output

The group of “transferred lines” includes all those that have been moved to the `EmLine` class.

In older versions of this document a large list of emission lines appeared here. This list is now far too large to include here. Rather, the list can be generated by executing the code with the command **save line data “filename.txt”** included. This will create a file that includes the full set of lines that are predicted. Note that the lines that are output are only those that exist when the code is run. It is possible to make many of the model atoms and molecules as large or small as you like, and the actual lines that exist when the **save** command is entered will be output. The test case `func_lines.in` in the test suite includes this save command and generates a list of all transferred lines in the file `func_lines.lis`.

To generate a line list, set up a calculation with the atoms set to whatever size is desired (see the **atom** command in Part I). Then execute this script with the **save line data** command included (described in Part I). The save output will include the line list. This will include the level 2, H and He iso-sequence, H₂, CO, and recombination lines, but not the scalar forbidden lines. These are described in a list following this subsection.

This contains several groups of lines. All quantities were evaluated at 10^4 K . The description of the command in Part I of this document explains how to evaluate the quantities at other temperatures.

The ion is the first column of the table. This is in a uniform format, beginning with the two character element symbol and followed by an integer indicating the level of ionization. “C 2” is C⁺ or C II. This is followed by the integer wavelength label used to identify the line in the printout. The third column, with the label “WL”, is the correct wavelength of the line, with units of microns (“m”), Angstroms (“A”), or cm (“c”). The remaining columns give the statistical

weights of the lower and upper levels, the product of the statistical weight and the oscillator strength, and then the transition probability.

The last column is the electron collision strength. Usually these collision strengths are for only the indicated transition, although in some cases (the Be sequence) the value is for the entire multiplet.

9.3.2 Output produced for the transferred lines

Because the lines have a common format within their storage vectors, the output has a common format too. Generally only the total intensity of the transition, the result of the solution of a multi-level atom with all processes included, is printed. The approach used to compute the level populations is described in Part II of HAZY, and includes continuum pumping, destruction by background opacities, and trapping.

The total intensity of the transition is printed in a form like “C 2 1335”, with the spectroscopic identification given by the first part, as found in the first column of the table, and the wavelength as indicated by the number in the second column of the table.

In a few cases (for instance, the C IV $\lambda\lambda$ 1548, 1551 doublet), a total intensity is also derived. In these cases the label “Blnd” will appear together with an average wavelength (1549 in this case). These lines are all explicitly shown in a following section.

It is possible to break out various contributors to the lines with options on the **print line** command, described in Part I of this document and in the following. These contributors are printed following the total intensity.

print line heating An emission line will heat rather than cool the gas if it is radiatively excited but collisionally de-excited. The print out will include this agent, with the label “Heat”, when this command is given.

print line collisions The collisional contribution to the lines will be printed, with the label “Coll”.

print line pump The contribution to the total line, produced by continuum pumping, is printed with the label “Pump”. What is observed? Whether or not this is a net emission process contributing to the observed line intensity depends on the geometry, mainly whether or not continuum source is in the beam. At some velocities within the line profile this can be a net emission process, due to absorption at other velocities. If the continuum source is in the beam and gas covers it, this is not a net emission process, since photons are conserved.

print line inward The inwardly directed part of the total emission is printed with the label “Inwd”. This can be greater than half of the line intensity if the line is optically thick since these lines tend to be radiated from the hotter illuminated face of the cloud.

print line optical depths At the end of the calculation the optical depths for all optically thick lines will be printed. This is not done by default since it can be quite long.

9.4 Line identifications

The file `line_labels.txt` in the docs directory of the distribution lists line identifications and a brief description of its origin.

Table 9.2: Hydrogen emission lines

Series	$n' \rightarrow n$	Wavelength	$I(\text{Case B})$
Lyman	2-1	1215.68A	-
Balmer H α	3-2	6562.85A	2.8463
H β	4-2	4861.36A	1.0000
H γ	5-2	4340.49A	0.4692
H δ	6-2	4101.76A	0.2596
Paschen P α	4-3	1.87511m	0.3319
P β	5-3	1.28181m	0.1617
P γ	6-3	1.09381m	0.0899
P δ	7-3	1.00494m	0.0553
Brackett Br α	5-4	4.05116m	0.0778
Br β	6-4	2.62515m	0.0445
Br γ	7-4	2.16553m	0.0274
Br δ	8-4	1.94456m	0.0180
Pfund	6-5	7.45781m	0.0246
Humphreys	7-6	12.3685m	0.0098
	8-7	19.0566m	0.0042
	9-8	27.7957m	0.0020

9.5 Hydrogen recombination lines

Table 9.2 gives the strongest lines of the lowest series. All lines have the label “H 1”. The wavelength column gives the string as it appears in the printout. “m” indicates a wavelength in μm and A in Angstroms. The Case B intensity is taken from the `limit_caseb_h_hs87` test case.

Some IR lines may have the same wavelength if the default line precision is used. The **set line precision** command can be used to increase the number of significant figures in the line wavelength, which should make identification easier.

9.6 Molecular hydrogen lines

Table 9.3 gives some of the stronger or more frequently observed H₂ lines. These are only predicted when the large model H₂ molecule is included with the **atom H2** command. The wavelength column gives the string as it appears in the printout. “m” indicated a wavelength in μm . All lines have the label “H2 ”.

Many lines will have the same wavelength if the default line precision is used. The **set line precision** command can be used to increase the number of significant figures in the line wavelength, which should make identification easier.

The following is an example which predicts the emissivity of the H₂ 2.121 1-0 S(1) μm line.

```
save line emissivity ``lines.ems``
H2 2.121m
end of lines
```

Table 9.3: Molecular hydrogen emission lines

Transition	ν_{hi}, J_{hi}	ν_{lo}, J_{lo}	$\lambda(\text{label})$	$\chi(\text{hi, K})$

Chapter 10

PROBLEMS

10.1 Introduction

The code is designed to be autonomous and self-aware. Nonetheless, it can run into problems. This section describes some of the errors that can cause CLOUDY to stop. Floating point errors should never occur. Several other internal errors, which the code is designed to trap and then complain about, could occur. Finally, it is possible that the code will stop because of convergence problems.

The most important single thing to understand about any calculation is why it stopped and whether this affects the predictions. This is discussed further in the section *Stopping Criteria*.

If the calculation aborts it will conclude with a request to post the information on the web site's discussion board—please do—we can't fix it if we don't know it's broken.

Please post any problems on the discussion board on the code's [discussion board](#).

10.2 Thermal stability and temperature convergence

This section describes thermal stability problems, how to identify them, and what to do about them.

10.2.1 Types of thermal maps

Three types of thermal maps, showing the heating or cooling of gas as a function of temperature, can be produced by CLOUDY. Each is the answer to a different question.

Figure 10.1 shows the heating and cooling rates as a function of temperature for a photoionized gas in which the gas kinetic temperature was varied. This figure was produced with the test case `func_map.in`, one of the standard test cases included in the code distribution. Both the gas density and the flux of ionizing photons were held constant and the kinetic temperature was varied. Only one temperature, the point where the two curves cross, occurs in equilibrium. The `func_map.in` file uses the **save map** command to determine heating and cooling rates at a variety of temperatures. This is exactly what the code does to determine the equilibrium temperature, so this plot can be useful to find out why the code ran into temperature convergence problems. This is why the command was introduced.

Figure 10.1: A typical heating—cooling function for low density photoionized gas. The cooling and heating rates ($\text{erg cm}^{-3} \text{ s}^{-1}$) are shown.

Figure 10.2: A typical cooling function for low density collisionally ionized gas.

Collisionally-ionized gas has a well-defined cooling rate that is only a function of temperature. The sample program `hazy_coolingcurve.cpp` (included in the `programs` directory in the code's distribution) does such a calculation, and Figure 10.2 shows the results. Here the kinetic temperature is set by some physics external to the calculation. The entire ionization solution is valid for each temperature under this assumption. The unspecified heat source would have to provide a local heating rate that is equal to the calculated cooling rate for the solution to be time steady.

The third map is the type of thermal stability map shown by [Krolik et al. \(1981\)](#) and plotted in Figure 10.3. The program that generated these results is given in the file `hazy_kmt.cpp`. Here the equilibrium temperature is determined self-consistently for gas over a wide range of densities, but for a single flux of ionizing photons (or equivalently, distance from the central object).

10.2.2 No Temperature Convergence

A temperature failure occurs when the heating-cooling balance is not within a certain tolerance, set by the **set temperature error** command, after 20 tries. Normally CLOUDY will punt after an excessive number of temperature failures occur. The limit to the number of failures is reset with the **failures** command. If the **failures map** command is entered then the code will first produce a

Figure 10.3: Equilibrium temperature as a function of density.

map of heating-cooling space to give an indication of where the equilibrium temperature should have been when excessive failures occur.

Temperature failures most often occur for temperatures in the range 10^2 K to 4×10^3 K, and 10^5 K to 10^6 K. These are where the cooling function permits more than one thermal solution (see, for example, Williams, 1967; Dalgarno and McCray, 1972).

Figure 10.1 shows a typical cooling function for gas in photoionization equilibrium. A peak is reached at a temperature near 10^3 K. This occurs when the fine-structure lines are major coolants. At lower temperatures their cooling rate increases exponentially (as expected), until roughly 10^3 K, when their Boltzmann factors are near unity. Above this temperature their cooling rate is nearly proportional to the Coulomb focusing factor $T^{-1/2}$, and the cooling *decreases* until the temperature is high enough for optical forbidden lines to become important (at roughly 4000 K). A similar phenomenon occurs near the $\sim 10^5$ K to 10^6 K peak in the cooling function.

When failures occur because more than one temperature solution is possible, the reported failures are a physical (not numerical) problem. CLOUDY will try to deal with this by forcing the temperature to values below the peak in the cooling function. Increasing the number of allowed failures (with the **failures** command) to prevent the code from stopping prematurely is permissible as long as the global energy balance is preserved. A warning will be issued at the end of the calculation if the heating-cooling balance is not preserved.

10.2.3 Thermal Stability

The thermal solution may be unstable when the temperature derivative of the net cooling function (cooling minus heating) is negative (Field, 1965). Possibly unstable solutions are indicated by a “u” just before the equilibrium temperature in the zone printout. The temperature derivative is for isochoric (constant density), not isobaric (constant pressure), conditions. Comments are printed at the end of the calculation if possibly unstable thermal solutions are present in the calculation.

10.2.4 Thermal fronts

Just as an ionization front is a region where the level of ionization changes dramatically over a small scale, a thermal front occurs where the temperature changes dramatically over a small scale. This can be caused by a real physical change of state of the gas such as those that occur near the peaks in the cooling curve. An example of a thermal front, taken from Ferland et al. (2002), is shown in Figure 10.4. This type of jump is physical. The gas changes phase and moves to different branches of the cooling curve. The code will generate a caution or comment if the electron temperature changes discontinuously from one zone to the next.

A thermal front can lead to pressure convergence failures when the solution jumps between the high and low temperature branches. Figure 10.5 shows an example case, taken from `orion_hii_pdr_pp.in` in the test suite. This shows the pressure history (output with the **save pressure history** command). The solver adjusts the density trying to make the resulting pressure agree with the desired pressure. The pressure changes continuously with density up to the point where the temperature jumps over the peak in the cooling curve. No solution is possible, and the code announces a pressure failure. In nature the presence of a magnetic field (added with the **magnetic field** command) will cushion the front from large changes in density.

Figure 10.4: An example of a thermal front in a cooling flow cloud (Ferland et al., 2002). The x-axis is the depth into the cloud (cm). The thermal front at $\sim 4 \times 10^{15}$ cm is unresolved.

Figure 10.5: A thermal front in a constant pressure simulation. The x-axis gives the density [cm^{-3}] and the y-axis is the pressure [dynes cm^{-2}]. The points forming the large box are the resulting total gas pressure and the horizontal line is the correct pressure. The solution jumps above and below the equilibrium value as the temperature jumps above and below the thermal front.

Figure 10.6: A constant-pressure thermal front in a temperature - radius plot. The x-axis gives the radius (cm). The y-axis gives the log of the temperature (K). The solution jumps above and below the equilibrium value, leading to a series of pressure failures, near a depth of 2×10^{17} cm, as it soldiers on through the thermal front.

A series of pressure failures occur in this simulation when the gas falls to a temperature of ~ 300 K, as shown in Figure 10.6. The code simply presses on with the goal of reaching the cold side of the front.

10.2.5 Map Output

The program stops if an excessive number of temperature failures occur. The default limit is 20. It will produce a map of the heating and cooling as a function of temperature for the last computed zone if the **map** option on the **failures** command is given. The map is described here. The start of the output from the test case `func_map.in` is shown below.

```
90.02x map of heating vs cooling
te, heating, cooling.
Cloudy punts, Te= 9.254E+03 HTOT= 9.123E-24 CTOT= 9.118E-24 nzone= 1
COOLNG array is

  Ne 5 24 0.010 Ne 5 14 0.009 C 3 1910 0.008 Heff 0 0.007 Si 2 34
Line heating array follows
  Te Heat-----> Cool-----> dH/dT dC/DT
1.0000E+01 3.4774E-22 1 1 0.636 4.6095E-26 H FB 0A 0.723 -8.19E-24 1.56E-27 9.1
1.0209E+01 3.4490E-22 1 1 0.635 4.6814E-26 H FB 0A 0.720 -7.98E-24 1.65E-27 9.1
1.0423E+01 3.4233E-22 1 1 0.635 4.7510E-26 H FB 0A 0.717 -7.74E-24 1.74E-27 9.1
```

The output begins with a listing of the strongest coolants for the last zone. Then the program steps through increasing temperatures and prints the heating, cooling, and ionization of the gas.

From this information it should be possible to determine the temperature where the equilibrium thermal solution should have been. Each solution is completely self-consistent, except that heating and cooling do not balance. Both the local attenuated radiation field and collisional ionization contribute to the ionization balance at each temperature. All processes contribute to the thermal balance, including collisional ionization. The map is at constant density.

The first column gives the temperature. Columns 2 and 6 give the volume heating and cooling. Both have units $\text{erg s}^{-1} \text{cm}^{-3}$. Columns 3 and 4 constitute an indication of the main heating source. Columns 7 and 8 give the label and wavelength of the strongest coolant. Columns 5 and 9 give the fraction of the total heating or cooling due to these agents. Columns 10 and 11 give the heating and cooling derivatives. Columns 12 and 13 give the electron and hydrogen densities (cm^{-3}) and the remaining columns give the logs of the hydrogen and helium ionization fractions. The location of the probable thermal solution is indicated by a comment surrounded by dashed lines.

10.3 Convergence problems with dust-free static sphere

Ionization convergence problems can occur with a dust-free static spherical geometry. The default geometry when the **sphere** command is entered is for lines to freely escape after crossing the central hole due to some level of expansion. In a static spherical geometry (set with the **sphere static** command) the total $L\alpha$ optical depth at the illuminated face of the shell will be very large since the line is scattered by the matter that lies across the entire shell. The line is destroyed when dust is present. If dust is not present the $L\alpha$ intensity J will become very large. If the total optical depth in $L\alpha$ is also large then the dominant escape / destruction process for the line will be absorption by atoms of third-row elements or the $n = 2$ level of hydrogen. This can lead to ionization convergence problems due to the extremely large $L\alpha$ intensity J .

The first question to ask is whether this geometry is appropriate. Dust is nearly always present in the ISM. In dense stellar environments it is unlikely that a spherical geometry will be static. Include dust, use the default expanding spherical geometry, or a wind, and the problem will go away. To the best of my knowledge this geometry does not occur in nature.

10.4 Optical depth convergence problems

The code generally will not converge if it has not done so within ten or so iterations. Convergence problems most commonly occur when the specified column density or thickness is very near a prominent ionization front. In this case very small changes in the physical conditions result in large changes in the optical depths. The code will not have convergence problems if an optical depth is used as a stopping criterion instead.

10.5 Negative populations

It is possible that the code will stop because negative level populations were predicted for atoms, ions, or molecules. This is not supposed to occur, but sometimes happens because of numerical

instabilities in the matrix inversion routine. Please post the input stream and version of CLOUDY on the code's discussion board.

10.6 Floating Point Errors

The code should be compiled and linked with options enabled so that the code will crash on overflow or division by zero, but ignore underflow. The **crash** command described in Part 1 tests this. *Floating point errors should never occur.* The logic within the code is designed to identify problems, and complain, but not fail. The logic is only as good as the tests they were designed to pass. It is inevitable that circumstances will occur for which the logic now in the code is not sufficient. It is possible that the code will fail when these circumstances occur. I would be grateful for reports of any such failures, since they inevitably identify shortcomings in the code, and lead to its improvement. Please post comments on the discussion board on the code's web site.

10.7 We can't fix it if we don't know it's broken

Machines are growing faster far more rapidly than people are getting smarter. Reliability in the face of complexity is the major challenge to the development of any large-scale computer code ([Ferland, 2001a](#)). There can be little doubt that CLOUDY contains bugs.

If problems arise or the code crashes then it is likely that you found a problem. We would appreciate learning about such problems since they identify shortcomings which usually lead to improvements in the code (or the documentation). Please post queries and bug reports on the discussion board on the code's discussion board.

Chapter 11

HISTORY AND ACKNOWLEDGEMENTS

11.1 History

CLOUDY was born at the Institute of Astronomy, Cambridge, in August of 1978, in the computing environment described in the web document <http://www.nublado.org/gary/computing1970s.htm>. Its development has been continued at The University of Kentucky, The Ohio State University, and during extended visits to the Joint Institute for Laboratory Astrophysics, the Royal Greenwich Observatory, IOA Cambridge, Cerro Tololo Interamerican Observatory, and the Canadian Institute for Theoretical Astrophysics.

The code has been through three computer languages. It was originally written in FORTRAN IV and advanced through several dialects, reaching FORTRAN 77 in 1994 (version 84). Version 90 was written in a mix of FORTRAN 77 and MILSPEC extensions. This was the most advanced Fortran that could be used with open source compilers. It moved to ANSI 89 C in 1999 (version 96) and to C++ with the release of 07.02 in 2007.

Moore's Law is due to Gordon Moore, one of the founders of Intel Corporation. He observed that modern CPU's become about twice as powerful every 18 months. This trend has held true for the past twenty years, shows no sign of failing, and seems to be associated with our ability to control complexity. By this standard the growth of CLOUDY has been conservative, in that it is growing slower and complex on the Moore's-law timescale. Figure 11.1 shows the evolution of the code, as indicated by its size as a function of time.¹ As another example, the Meudon 1985 Meeting planetary nebula test (**pn_paris.in** in the test cases) has always taken about one minute to compute.

11.2 Acknowledgments

Comments or suggestions which led to the improvement of CLOUDY were made by the many individuals acknowledged on the web site <http://www.nublado.org>.

Peter G. Martin and Hagai Netzer had special roles during the early development of the code. Peter added several of the commands that deal with ordering of supplemental line lists and the

¹Before mid-1995 the size was the total number of lines in the distributed source. After 1995 the size only includes the number of lines excluding block data. When the code was converted to C the block data were converted to external data files. These external files are now far larger than the code itself.

Figure 11.1: The size of the code as a function of time. The code grows roughly 7% larger per year, with growth spurts and slowdowns at times. There are several changes in slope evident - the year and cause are: 1985 - mainframe to Unix; 1993 - Unix to windows; the jump at 1999 - the Fortran to C conversion and the Williams / van Hoof drop in 2006, due to the use of object-like structures and moving converted fortran block data into separate files.

luminosity options on the **blackbody** command, insisted that CLOUDY run on a VAX, provided access to the University of Toronto VAX 11/780 during the 1980's, and more recently hosted the group at CITA during a sabbatical. Hagai and I have spent countless hours arguing over methods, assumptions, and just whose code had the bug. These comparisons are the only way to debug codes as large as CLOUDY or ION.

Peter van Hoof has gone over the code very carefully, finding many problems, and expanding its capabilities. The current version of the grain physics was developed by Peter together with Peter Martin, and Joe Weingartner. PvH developed the stellar library implementation in the current version. He is the maintainer for both the grains and stellar atmospheres codes.

The move to make the solvers far more rigorous and include dynamics and advection has been led by Robin Williams and Will Henney. Robin has rewritten the chemistry solvers to take advantage of the structures present in the C language and make them more robust.

The initial implementation of the hydrogen iso-electronic sequence was done by Jason Ferguson as part of his thesis. Ryan Porter developed the He-like isoelectronic sequence in his thesis. The expansion of the simulations into the PDR was done by Nick Abel and Gargi Shaw as part of their theses.

Sections of the code are taken from public domain software, as acknowledged in this document and in the source. Portions of the code were written by those listed in the `others.txt` file in the distributed files.

The preparation of the bibliographic references in this document made use of data from the NASA's Astrophysics Data System Bibliographic Services.

The development of CLOUDY would not have been possible without twenty nine years of continuous support by The National Science Foundation. This began with AST 80-2522, and has been continued with grants 83-05094, 85-12414, 87-19607, 90-19692, 93-19034, 96-17083, 00-71180, 03-0772, and most recently AST 06-07028. NASA has supported CLOUDY through ATP program awards NAG5-12020 and NNG05GD81G. Support from the University of Kentucky Center for Computational Sciences is also gratefully acknowledged.

Appendix A

ATOMIC DATA SOURCES

Codes like CLOUDY can only exist because of the large body of work done by the atomic and molecular physics community. This work will only continue to be supported if it is cited in the literature whenever it is used. The following is a partial list of citations for the atomic data used within the code.

This table is generated by the perl script `doc_atomic_data.pl`. This generates the file `doc_atomic_data_refer.txt` which is pasted below.

Appendix B

GLOSSARY OF SYMBOLS

As far as possible, the notation used by HAZY follows standard texts (AGN3; [Mihalas, 1978](#)). This is a summary of some of the symbols used.

The fundamental constants used by the code are from the [CODATA recommended values](#). Constants are contained in the header `physconst.h`.

Symbol	Description	Units	Notes
a	Stefan radiation density	$\text{erg cm}^{-3} \text{ K}^{-4}$	7.56464×10^{-15}
a	damping constant	—	
a_o	Bohr radius	$\hbar/m_e c^2 \text{ cm}$	$0.5291775 \times 10^{-8}/Z$
A_{rad}	radiative acceleration	cm s^{-2}	
A_{ul}	radiative rate from level u to l	s^{-1}	
b_n	departure coefficient	—	
B	magnetic field	esu	
B_ν	Planck function	$\text{erg cm}^{-2} \text{ s}^{-1} \text{ Hz}^{-1} \text{ sr}^{-1}$	
c	speed of light	cm s^{-1}	2.997925×10^{10}
C	collisional rate	s^{-1}	
C_{ul}	line collision rate	s^{-1}	
D_{ul}	line destruction probability	—	
f	oscillator strength	—	
$f(r)$	filling factor	—	
f_ν	flux density	$\text{erg cm}^{-2} \text{ s}^{-1} \text{ Hz}^{-1}$	
F_ν	flux density	$\text{erg s}^{-1} \text{ Hz}^{-1}$	
g	grain asymmetry factor	—	
g_i	statistical weight	—	
g_{III}	T aver free-free gaunt factor	—	
g_\odot	Solar surface gravity	cm s^{-2}	2.74×10^4
G	gravitational constant	$\text{dyne cm}^2 \text{ g}^{-2}$	6.673×10^{-8}
G	energy gains, heating	$\text{erg cm}^{-3} \text{ s}^{-1}$	
h	Planck's constant	erg s	6.6262×10^{-27}
\hbar	Planck's constant	erg s	1.0546×10^{-27}
I	integrated intensity	$\text{erg s}^{-1} \text{ sr}^{-1} \text{ Hz}^{-1}$	
I_n	ionization potential of level n	erg Ryd	

I_V	intensity	$\text{erg s}^{-1} \text{ sr}^{-1} \text{ Hz}^{-1}$	
J	integrated mean intensity	$\text{erg s}^{-1} \text{ sr}^{-1}$	
J_V	mean intensity	$\text{erg s}^{-1} \text{ sr}^{-1} \text{ Hz}^{-1}$	
k	Boltzmann constant	eV deg^{-1}	8.6171×10^{-5}
k	Boltzmann constant	erg deg^{-1}	1.38062×10^{-16}
L_\odot	luminosity of sun	erg s^{-1}	3.826×10^{33}
m_A	mass of atom A	gm	
m_{AMU}	atomic mass unit	gm	$1.6605402 \times 10^{-24}$
m_e	electron mass	gm	9.10956×10^{-28}
$m_e c^2$	electron energy	Ryd	3.75584×10^4
m_p	proton mass	gm	$1.6726231 \times 10^{-24}$
M_J	Jeans' mass	gm	
M_\odot	mass of the sun	gm	1.989×10^{33}
M_\oplus	mass of the Earth	gm	5.977×10^{27}
n_e	electron density	cm^{-3}	
n_j	population of level j	cm^{-3}	
n_p	proton density	cm^{-3}	
$n(H)$	total H density, all forms	cm^{-3}	
$n(x)$	density of species x	cm^{-3}	
$n(cr)$	cosmic ray density	cm^{-3}	
n	atom's level	—	
$n(H_{\text{tot}})$	H density, all forms	cm^{-3}	
$N(x)$	column density of species x	cm^{-2}	
$N(H_{\text{tot}})$	total H col den, all forms	cm^{-2}	
N_{eff}	effective H column density	cm^{-2}	
$P_*(x)$	LTE relative population	cm^3	
P_{gas}	gas pressure	dyn cm^{-2}	
P_{lines}	line radiation pressure	dyn cm^{-2}	
P_{tot}	total pressure	dyn cm^{-2}	
P_{ul}	line escape probability	—	
$P_{\tau x}(n)$	continuum escape prob	—	
pc	parsec	cm	3.085678×10^{18}
q_{ij}	line collisional rate coefficient	$\text{cm}^3 \text{ s}^{-1}$	
q_n	collisional rate coefficient	$\text{cm}^3 \text{ s}^{-1}$	
q_e	electron charge	esu	4.80325×10^{-10}
Q_{abs}	grain absorption efficiency	—	
$Q(H)$	hydrogen ionizing photons	s^{-1}	
r	radius	cm	
$r_{l,u}$	rate	s^{-1}	
R_0	inner radius	cm	
R	total to selective extinction	—	
R_H	Rydberg unit for H	—	
R_∞	Rydberg unit for inf mass	—	
R_{AU}	radius of Earth's orbit	cm	1.4959×10^{13}

R_+	radius of the Earth	cm	6.378×10^{18}
R_\odot	radius of the sun	cm	6.9599×10^{10}
T_e	electron temperature	cm^{-3}	
$T_{eff}(\odot)$	Sun's effective temperature	K	5770 K
T_{exc}	excitation temperature	K	
T_{color}	color temperature	K	
T_{low}	lowest temp allowed	K	2.8 K
T_u	energy density temperature	K	
u	energy density	erg cm^{-3}	
U_g	grain potential	volt	
u	velocity (mean or projected)	cm s^{-1}	
\bar{u}	mean particle speed	cm s^{-1}	
u_{Dop}	Doppler velocity	cm s^{-1}	
u_{exp}	expansion velocity	cm s^{-1}	
u_{th}	thermal velocity	cm s^{-1}	
u_{turb}	turbulent velocity	cm s^{-1}	
V_g	grain potential	eV	
V_n	grain work function	eV

CONVERSION FACTORS

Table [C.1](#) gives conversion factors between various common units. The last column of the table gives the variable names for constants that occur within the code. Most are defined as macros within the header file **physconst.h**. These should be used instead of entering the constant directly. In the following all Rydbergs are for infinite mass nuclei.

The fundamental constants used by the code are from the [CODATA recommended values](#) and are in the header file `physconst.h`. Derived quantities should be formed from the fundamental quantities given there, so that any future changes will trickle down into all parts of the code.

Table C.1: Conversion Factors

To convert from	Variable	to	multiply by	Parameter
AU		cm	1.49597870(13)

THE TEST SUITES

D.1 Introduction

The code must be completely tested every time anything is changed. This is done with the test suite that is included in the distribution. The following pages list the test cases included in the `auto` directory within the test suite directory `tsuite`.

The test suite contains a series of Perl scripts that automate several tasks. The `readme_tests.htm` file included with the tests describes these scripts. The script `doc_tsuite.pl` extracts the test names and the description of each, and creates two files, `doc_tsuite.htm`, a formatted description of each test, and `doc_tsuite.txt`, the table that follows this discussion.

The test cases include a large number of **monitor** commands that allow the code to be automatically tested every night. These **monitor** commands have been removed from the examples below.

The simulations form various classes. The names of the classes and their intention is given in Table [D.1](#).

D.2 Organization of commands

Commands can (mostly) occur in any order but we have made an effort to enter them in the order shown below. This is so that they can be studied to see examples of how to use the code.

commands controlling continuum

commands for density & abundances

commands controlling geometry

other commands for details

commands controlling output As indicated, there are the **print** and **save** commands which control the code's output.

commands giving the monitors Each test includes a number of **monitor** commands. These give values of predicted quantities that the code has obtained in the past. Changes to the code may cause predicted values to change, and if they do the **monitor** command will announce it.

Table D.1: Keywords used in the Test Suite.

Class	Function
Blr	Broad emission line region of AGN
Coronal Dynamics	Collisionally ionized gas with pre-set temperature Flow
Function	Test various functions of the code
Geometry	Test geometric aspects, aperture command
HII	H II regions
IGM	Intergalactic medium
ISM	Interstellar medium
Limit	Test limiting cases
NLR	Narrow-lined region of AGN
Nova	Aspects of the classical nova explosion
Optimizer	Test the optimizers
PDR	Photodissociation region
PN	Planetary nebulae
Stars	Stellar atmospheres

D.3 The Auto Test Suite

Table D.2 lists the simulations in the `auto` test directory.

Table D.2: The simulations in the auto test suite.

Class	Function
agn_blr_albedo	measure Rayleigh scattering of Ly α
agn_lex00_u0	intermediate-ionization x-ray ionized cloud from Lexington 2000
agn_lex00_u1	high-ionization x-ray ionized cloud from Lexington 2000
agn_lex00_um1	low-ionization x-ray ionized cloud from Lexington 2000
agn_reflector	model of Compton reflector
agn_S_curve_grid	temperature across Spitzer thermal stability S curve
agn_warm_absorber	simple warm absorber model
agn_warm_absorber_hiU	simple warm absorber model
aperture_beam_int	test aperture beam command with intensity
aperture_beam_lum	test aperture beam command with luminosity
aperture_slit	test aperture slit command with luminosity
blr_f92	standard blr cloud in Ferland et al. 1992
blr_fp89	final F+P 1989 BLR model table 3
blr_hizqso	high Z quasar cloud
blr_kk81	old blr
blr_level2	test dominant level2 lines
blr_n09_p18	BLR model, density 1e09 cm ⁻³ , flux of H-ion photos 1e18 cm ² s ⁻¹
blr_n09_p18_Z20	BLR model, density 1e09 cm ⁻³ , flux of H-ion photos 1e18 cm ² s ⁻¹ , Z=20

Continued on next page

Table D.2: (continued)

Class	Function
blr_n09_p20	BLR model, density 1e09 cm-3, flux of H-ion photos 1e20 cm2 s-1
blr_n09_p20_Z20	BLR model, density 1e09 cm-3, flux of H-ion photos 1e20 cm2 s-1, Z=20
blr_n09_p22	BLR model, density 1e09 cm-3, flux of H-ion photos 1e20 cm2 s-1
blr_n09_p22_Z20	BLR model, density 1e09 cm-3, flux of H-ion photos 1e22 cm2 s-1, Z=20
blr_n11_p20	BLR model, density 1e11 cm-3, flux of H-ion photos 1e20 cm2 s-1
blr_n11_p20_Z20	BLR model, density 1e11 cm-3, flux of H-ion photos 1e20 cm2 s-1, Z=20
blr_n12_p19	BLR model, density 1e12 cm-3, flux of H-ion photos 1e19 cm2 s-1
blr_n12_p19_Z20	BLR model, density 1e12 cm-3, flux of H-ion photos 1e19 cm2 s-1, Z=20
blr_n13_p18	BLR model, density 1e13 cm-3, flux of H-ion photos 1e18 cm2 s-1
blr_n13_p18_Z20	BLR model, density 1e13 cm-3, flux of H-ion photos 1e18 cm2 s-1, Z=20
blr_n13_p22	BLR model, density 1e13 cm-3, flux of H-ion photos 1e22 cm2 s-1
blr_n13_p22_Z20	BLR model, density 1e13 cm-3, flux of H-ion photos 1e18 cm2 s-1, Z=20
blr_n14_p18	BLR model, density 1e14 cm-3, flux of H-ion photos 1e18 cm2 s-1
blr_n14_p20	BLR model, density 1e14 cm-3, flux of H-ion photos 1e20 cm2 s-1
blr_n14_p22	BLR model, density 1e14 cm-3, flux of H-ion photos 1e22 cm2 s-1
blr_nf84	early model of blr
blr_nf84_45deg	early model of BLR, with illumination at 45 degree angle
blr_rnfa	table 1 of Rees et al. ApJ 347, 648
blr_rnfb	table 1 of Rees et al. ApJ 347, 648
chianti_all_cool	cooling of a collisionally ionized plasma
chianti_fe_cool	cooling of a collisionally ionized plasma
coll_coronal	model of active region of solar corona
coll_heat_only	test code in limit where ONLY mechanical heating is present
coll_t3	coronal equilibrium at 10^3 K
coll_t3_grains	coronal equilibrium at 10^3 K, with grains to assist chemistry
coll_t4	coronal equilibrium at 10^4 K
coll_t4_Z30	coronal equilibrium at 10^4 K
coll_t5	coronal equilibrium at 10^5 K
coll_t6	coronal equilibrium at 10^6 K
coll_t7	coronal equilibrium at 10^7 K
dynamics_orion_flow	Orion nebula blister with wind
dynamics_veryfast	very fast wind model
dynamics_veryfast_rec	very fast wind model
dynamics_wind	test of equations of motion in a very highly ionized wind
feii_hin	test feii in high density limit

Continued on next page

Table D.2: (continued)

Class	Function
feii_hirad	feii in case of high radiation density limit
feii_pump	test feii in continuum pumped limit
feii_ste	thermal equilibrium of FeII in STE limit
feii_t4n0	FeII emission in typical intermediate density photoionized cloud
feii_t4n8	FeII emission in typical intermediate density photoionized cloud
feii_t4n8_rt	FeII emission in typical intermediate density photoionized cloud
feii_t4n8_Smyth19	FeII emission in typical intermediate density photoionized cloud
feii_t4n8_Tayal18	FeII emission in typical intermediate density photoionized cloud
feii_t4n8_Verner99	FeII emission in typical intermediate density photoionized cloud
func_abund_fluc	check fluctuating heavy-element abundances
func_distance	check that distance and "print flux earth" commands work
func_dlaw	test model with dlaw table
func_fulltrace	test full trace output
func_globule	test of globule command
func_grid_line_ratios	test generating line ratios in a grid run
func_grid_list	test the 'list' keyword on the grid command
func_hotgas_coolstar	test very soft continuum, very hot gas
func_ion_increase	test model where ionization increases with depth
func_LineList_PDR	check that wavelengths agree at high line precision
func_LineList_PDR_H2	check that wavelengths agree at high line precision
func_lines	create output file with list of func_lines
func_ly_pump_scale	test scaling of H lyman-line pumping
func_map	map of heating vs cooling
func_nolight	check OK with no radiation incident
func_sdrmin	test set drmin command
func_set_ion	test impact of setting ionization
func_stopcol	test stop column density "species" command
func_stopline1	test stop line command
func_stopline2	test stop line command
func_t10	test very soft continuum, very hot gas
func_t3	test low temperature limit of code, 3K
func_t3_linesintroff	test low temperature limit of code, 3K
func_t3_linesoff	test low temperature limit of code, 3K
func_test	run smoke test
func_test_cycle	exercise full range of density, temperature
func_test_grid	test whether the output from a repeated model reproduces exactly
func_testmole	this runs the standard, one command, test, which contains many asserts
func_tlaw	test model with tlaw table
func_trans_lumi	test transmitted continuum in luminosity mode

Continued on next page

Table D.2: (continued)

Class	Function
func_trans_read	second of func_trans_save/func_trans_read pair, use transmitted continuum
func_trans_read_lumi_scale	test read transmitted continuum in luminosity mode
func_trans_read_scale	second of func_trans_save/func_trans_read pair
func_trans_save	first of func_trans_save/func_trans_read pair, save continuum
func_trans_save_lumi	test save transmitted continuum in luminosity mode
grains_hot	test temperature of gas and dust in high energy density environment
grains_hot_wd01	test temperature of gas and dust in high energy density environment
grains_lte	check that grains equilibrate at correct temp in ste limit
grains_qheat	cool atomic ISM with Si grain quantum heating
grains_temp	test all grain species temperature
grains_temp_all	test all grain species temperature
grid_coronal	coronal equilibrium
grid_coronal_grains	coronal equilibrium
grid_coronal_primal	coronal equilibrium
grid_h2coronal	coronal equilibrium
grid_h2coronal_primal	coronal equilibrium
h2_coll_t4	coronal equilibrium at 10^4 K
h2_cr	H2 with background cosmic ray ionization
h2_cr_grains	background cosmic ray ionization by suprathermal electrons only
h2_hminus	H2 populations in H- dominated limit
h2_pdr_leiden_f1	low density and flux model 1
h2_solomon	H2 populations in solomon dominated limit
h2_t2000	test large H2 molecule in shock-like conditions
h2_t500	test large H2 molecule in PDR-like conditions
h_otsopen	test ots, inward fractions for pure hydrogen, open geo, filling factor
h_otspp	plane parallel conservation and hydrogenic emission for pure hydrogen
h_otssp	spherical conservation and hydrogenic emission for pure hydrogen
h_outopen	test open geometry
h_outpp	plane parallel H-only, close, test hydrogenic emission
h_outsp	spherical conservation and hydrogenic emission for pure hydrogen
h_t4_conemis	continuous emission from H atom
h_t4_conemis_lon	low-den continuous HI emission with 2-nu important
h_t4_conemis_thick	H I continuous emissivity, used for plot in hazy
heatomt10	continuous emission from HeI
heatomt10lon	test low-den continuous emission from H atom, 2-nu is important
heiont10	continuous emission from HeII
helike_ar	He-like argon emission
helike_c	he-like carbon emission
helike_co	He-like cobalt emission

Continued on next page

Table D.2: (continued)

Class	Function
helike_cu	He-like copper emission
helike_fe	he-like iron emission
helike_mg	he-like magnesium emission
helike_n	He-like nitrogen emission
helike_ne	he-like neon emission
helike_ni	he-like nickel emission
helike_o	he-like oxygen ion vs. Bautista & Kallman 2000 Table 1, column 3
helike_si	He-like silicon emission
helike_zn	He-like zinc emission
hhe_otssp	plane parallel conservation and H-like emission for H, He
hhe_otssp	spherical conservation and H-like emission for H and He
hhe_outpp	plane parallel conservation emission for H, He gas
hhe_outppff	plane parallel filling factor pure H, He gas
hhe_outsp	spherical conservation and H-like emission for H, He
hii_blister	Lexington 1995 dust-free hii blister region
hii_coolstar	dust free cool HII region model, Lexington 1995
hii_hiU_StaticSphere_noGrains	very high ionization parameter static H II region without dust
hii_hiU_StaticSphere_noGrains	test
hii_icf	HII region with negative He/H ICF
hii_paris	”New” Paris meeting HII region
hii_Um3	H II region sim from Christophe Morriset’s ionization paramter family
hii_Um35	H II region sim from Christophe Morriset’s ionization paramter family
hii_Um385	H II region sim from Christophe Morriset’s ionization paramter family
hlike_c	H-like C VI case B
hlike_o	H-like O VIII case B
igm_alpha	Ly alpha forest cloud
igm_alpha_hm12	Ly alpha forest cloud
igm_alpha_noisob	Ly alpha forest cloud
igm_alpha_noisob_hm12	Ly alpha forest cloud
igm_perseus	Perseus cluster
igm_primal	cloud with primordial abundances exposed to background at Z=10
igm_z3	redshift 1000 recombination epoch
igm_z3_thick	redshift 1000 recombination epoch
ism	cloud irradiated by ism background
ism_cosmicray	background cosmic ray ionization by suprathermal electrons only
ism_grid	interstellar cloud irradiated by ism background
ism_hot_brems	generate continuum due to hot ism in high Z,z starburst
ism_jura	check rate H2 forms on grain surfaces

Continued on next page

Table D.2: (continued)

Class	Function
ism_opacity	generate standard ISM opacity curve
ism_set_cr_rate	background cosmic ray ionization by suprathermal electrons only
limit_casea_h_den13	case A
limit_casea_h_den_temp	Test model H in Case A limit
limit_caseb_h_den10_temp45	the best we can do to predict the H I emission spectrum
limit_caseb_h_den2_temp37	the best we can do to predict the H I emission spectrum
limit_caseb_h_den2_temp4	the best we can do to predict the H I emission spectrum
limit_caseb_h_den2_temp45	the best we can do to predict the H I emission spectrum
limit_caseb_h_den2_temp5	the best we can do to predict the H I emission spectrum
limit_caseb_h_den2_temp5_coronal	the best we can do to predict the H I emission spectrum
limit_caseb_h_den4_temp45	the best we can do to predict the H I emission spectrum
limit_caseb_h_hs87	”Case B from Hummer and Storey”
limit_caseb_h_lot	log density case B, $T=500 \log n=2$
limit_caseb_h_n8	h_caseb_n8 high density case B
limit_caseb_he2_den8	limit_caseb_he2_den8 He II case B
limit_caseb_he_den	Test model H and He atoms in Case B limit
limit_caseb_he_den2_temp4	the best we can do to predict the HeI emission spectrum
limit_caseb_he_den4_temp4	the best we can do to predict the HeI emission spectrum
limit_caseb_he_den4_temp4_Fuji	the best we can do to predict the HeI emission spectrum
limit_caseb_he_den4_temp4_VR62	the best we can do to predict the HeI emission spectrum
limit_caseb_he_den4_temp4_VS80	the best we can do to predict the HeI emission spectrum
limit_caseb_he_den_temp	Test model He atoms in Case B limit
limit_caseb_hhe_den	Test model H and He atoms in Case B limit
limit_caseb_hhe_den_temp	Test model H and He atoms in Case B limit
limit_casec_h_den2	H only optically thin in Lyman continuum
limit_casec_h_den5	case C
limit_compton_hi_t	test high-T Compton energy exchange
limit_compton_lo_t	test low-T Compton energy exchange
limit_compton_mid_t	mid-T Compton energy exchange
limit_conserve	test that energy is limit_conserved
limit_eden	Martin Gaskell’s funny model
limit_h_induc	constant temper black body limit from Ferland and Rees 1988
limit_hi_ion	very high ionization parameter limit
limit_laser_1	test of H ionization in optically thin limit
limit_laser_2	test of H and HeI ionization in optically thin limit
limit_laser_200	ionization in Auger-dominated limit
limit_laser_200_low	test ionization in Auger-dominated limit
limit_laser_3	test H and He ionization in optically thin limit
limit_lowd0	test low density limit
limit_lowden	test optically thin model that extends to very low densities
limit_lowdm6	test low density limit

Continued on next page

Table D.2: (continued)

Class	Function
limit_lowion	test conditions of very low ionization matrix solver
limit_lte_h_t50_cion	collisionally ionized H in LTE limit
limit_lte_h_t50_coll	collisionally excited H in LTE limit
limit_lte_he1_coll	He atom at high densities
limit_lte_he1_nomole_iso_force	He atom in LTE at high densities, with no molecules, iso forced to LTE
limit_lte_he1_nomole_ste	He atom in LTE at high densities, with no molecules
limit_lte_he1_nomole_ste_nocoll	He atom in LTE at high densities, with no molecules and no collapsed levels
limit_lte_he1_nomole_ste_nocoll2	He atom in LTE for a large range of Te and density, with no molecules and no collapsed levels and no collisions
limit_lte_he1_ste	He atom in LTE at high densities
limit_lte_hhe_coll_t50	H, He in LTE at high densities
limit_lte_hhe_induc	radiation dominated H, He gas goes to STE
limit_lte_hhe_ste	H, He in STE
limit_lte_hminus	H- goes to LTE
limit_lte_metal	STE with metals
limit_recoil_ion	test compton recoil ionization of hydrogen
limit_strom	pure-H Stromgren sphere
limit_supra	secondary ionization dominated gas
limit_thick_brems	optically thick brems
limit_vbhum	compare with Van Blerkom and Hummer exact RT results
limit_veryveryfast	very fast simulation for Purify/valgrind
lya-21cm-constant	test effect of lya pump on spin temperature
lya-21cm-excitation	test effect of lya pump on spin temperature
lya-21cm-kinetic	test effect of lya pump on spin temperature
nlr_lex00	NLR model for Lexington 2000 Meeting
nlr_liner	NLR liner model
nlr_liner_grains	liner model with grains
nlr_paris	Paris meeting NLR model
nova_dqher	cold nova shell
nova_photos	dense nova photosphere
optimize_phymir	test phymir optimizers
optimize_subplex	test subplex optimizer
orion_hii_open	conditions similar to Orion nebula blister
orion_hii_pdr	constant pressure H+ region/pdr
orion_hii_pdr_fast	constant gas pressure H+ region/PDR
pdr_co_fully	H2 and CO in fully molecular limit
pdr_co_fully_noneq	H2 and CO are fully molecular, non-equilibrium case
pdr_coolbb	illumination by cool STE blackbody
pdr_dense_persei	dense phase zeta persei cloud

Continued on next page

Table D.2: (continued)

Class	Function
pdr_HTT91	low-density PDR from HTT91
pdr_leiden_f1	Leiden meeting model 1
pdr_leiden_f2	Leiden meeting model 2
pdr_leiden_f3	Leiden meeting model 3
pdr_leiden_f4	Leiden meeting model 4
pdr_leiden_hack_f1	Leiden meeting model 1 with hacks
pdr_leiden_hack_f2	Leiden meeting model 2 with hacks
pdr_leiden_hack_f3	Leiden meeting model 3 with hacks
pdr_leiden_hack_f4	Leiden meeting model 4 with hacks
pdr_leiden_hack_v1	Leiden meeting model 5 with hacks
pdr_leiden_hack_v2	Leiden meeting model 6 with hacks
pdr_leiden_hack_v3	Leiden meeting model 7 with hacks
pdr_leiden_hack_v4	Leiden meeting model 8 with hacks
pdr_leiden_v1	Leiden meeting model 5
pdr_leiden_v2	Leiden meeting model 6
pdr_leiden_v3	Leiden meeting model 7
pdr_leiden_v4	Leiden meeting model 8
pdr_minimal	test physical conditions at the illuminated face of a PDR
pdr_orion_veil	Orion's veil
pdr_th85ism	TH85 PDR with ISM grains
pdr_th85ism_cgto	TH85 pdr with ISM grains and C & O
pdr_th85orion	TH85 PDR with Orion grains
pn_fluc	Paris PN with density fluctuations
pn_ots	Paris PN with ots
pn_paris	"Paris meeting PN"
pn_paris_cpre	"Paris meeting PN with constant pressure"
pn_paris_fast	Paris PN, fast version
pn_sqrden	PN with density propt R^2 and filling factor
rrc_o	he-like oxygen ion vs. Bautista & Kallman 2000 Table 1, column 3
stars_atlas	Atlas stellar atmosphere
stars_atlas_3d	Atlas stellar atmosphere, 3D interpolation
stars_atlas_all	interpolate on Atlas grids
stars_atlas_odfnew_all	access various Atlas ODFNEW grids
stars_bstar2006	tlusty bstar grid
stars_bstar2006_3d	tlusty bstar grid
stars_bstar2006_all	tlusty bstar grid
stars_costar1	costar interpolation mode 1
stars_costar2	costar interpolation mode 2
stars_costar3	costar interpolation mode 3
stars_costar4	costar interpolation mode 4
stars_costarhalo	costar halo abundances

Continued on next page

Table D.2: (continued)

Class	Function
stars_kurucz79	Kurucz 1979 SED
stars_mihalas	Mihalas SED
stars_obstar_merged	tlusty bstar grid
stars_obstar_merged_3d	tlusty bstar grid
stars_obstar_merged_all	tlusty bstar grid
stars_optimize1	optimizer on stellar grids
stars_optimize2	optimizer on stellar grids
stars_optimize3	optimizer on stellar grids
stars_ostar2002	tlusty O star grid
stars_ostar2002_3d	tlusty Ostar grid
stars_ostar2002_all	tlusty Ostar grid
stars_rauch_3d	Rauch 3-dimensional grid
stars_rauch_cowd	Rauch hot PN star
stars_rauch_h+he	Rauch PN central star
stars_rauch_h-ca	Rauch central star hot PN
stars_rauch_h-ni	Rauch hot PN star
stars_rauch_helium	Rauch hot PN star
stars_rauch_hydr	Rauch hot PN star
stars_rauch_pg1159	Rauch hot [WR] PN
stars_rauch_pg1159_ascii	Rauch cool [WR] PN
stars_starburst99	Starburst 99 SED
stars_starburst99_2d	Starburst 99 2D SED
stars_werner	Werner stars grid
stars_wmbasic	wmbasic stellar SED
thin	"Thin coronal model"
time_cool_cd	constant density cooling cloud
time_cool_cd_eq	constant density equilibrium cooling cloud
time_cool_cd_flux	constant density cooling cloud
time_cool_cd_noaccu	constant density cooling cloud

This model computes the albedo of a fairly standard BLR cloud. This is the type of model that was presented in the BLR albedo paper by Korista & Ferland, 1998, ApJ 495, 672.

The asserts then check that these continua have the expected brightness.

```

This is one of the "warm absorber" simulations presented at the Lexington 2000 meeting on nebulae. Pequignot et al. summarized in 2001ASPC..247..533P. It is necessary to also include the command no induced processes to obtain the results presented there. This disables UTA ionization, a process that was not included in the calculations presented in the paper.

This is a model of the Compton reflector in AGN. It is a constant temperature since models of this region often make that assumption. A plot in Part I of Hazy shows the incident and reflected portions of the continuum. The code will complain that the cloud is Compton thick since it is not really designed to simulate this situation.

This is a homogeneous sphere that is especially simple. The model is a test of the aperture command, a command that simulates observing part of an extended object. In this case the aperture is a beam centered on the center of the nebula, with a line of sight extending through the object.

The code carries along a dummy emission line ("Unit 1") with a constant intensity of $1\text{e-}10\text{ erg cm}^{-3}\text{ s}^{-1}$. The line goes through all of the code's infrastructure, and when the calculation is complete, the program confirms that the "luminosity" of the line is the emitting volume times $1\text{e-}10$. The aperture command is verified by asserting that the emission line has the correct "luminosity". In this case the inner radius is not specified so the returned value is unity.

This is similar to one of the BLR models presented in Ferland et al. (1992) for the well-studied Seyfert galaxy NGC 5548. It has a very large column density and is marginally optically thick to electron scattering. The spectrum is given relative to Ly α , and the intensity of this line is reset to produce a spectrum that is on the same intensity scale as that paper.

```

Ferland and Persson (1989) presented this calculation of a BLR cloud. The differences between the present predictions and those given by FP are largely due to improved treatment of Balmer line escape and destruction. The spectrum is given relative to a Lya intensity of 100. The column density is VERY large, to reproduce intensities of low-ionization lines, especially the Ca II lines.

This is a model of a very high metallicity BLR cloud. It checks the intensities of some of the brighter lines, and is a check that the code can converge a cloud with this high Z.

Secondary ionization is very important when H is highly ionized, due to very high He abundance. Sec ionization becomes important at the $\text{He}^+ - \text{He}$ ionization front, where H^+/H is $1\text{e-}5$.

This is the "standard" BLR model presented by Kwan and Krolik (1981).

>>refer blr cloud Kwan, J., & Krolik, J. 1981, ApJ, 250, 478

Compare line intensities to previous versions of CLOUDY by entering into table on page Error! Bookmark not defined..

The code caution that the resulting total pressure was not constant is to be expected. The KK calculation assumed constant gas pressure, but internally generature line radiation pressure is significant. Because of this the sum of gas plus radiation pressure was not constant although the gas pressure was.

This is one of the 5 models that sample the LOC plane.

2010 dec 25 This sim obtains different results for Hb and Fe II with gcc and icc. This is because the sim is not fully converged. Robin's & Peter's notes follow. This will probably be trac ticket #191

results changed with trivial changes in the source - Peter's example follows; This is due to lack of convergence rather than a fundamental difference in physics r4426:

Fe 2 2400A 6.854 1.9161 Fe 2 6200A 6.827 1.8005 Fe 2 2500A 6.984 2.5834 Fe 2 2300A 7.101 3.3854 Fe 2 8900A 6.714 1.3899

r4427:

Fe 2 2400A 6.852 1.9092 Fe 2 6200A 6.923 2.2472 Fe 2 2500A 6.943 2.3504 Fe 2 2300A 7.161 3.8897 Fe 2 8900A 6.671 1.2574

Robin: OK, I ran for 10 iterations with an old vs. new test on the cooling -- no substantial differences were reported.

The ne does seem to wander around quite a bit deep in the model, rather than smoothly converge -- attached plot is for the last iterations 5 to 10 (i.e. from when the code declares convergence in the standard blr_... run onwards). Not so bad as the difference plot which Peter shows, but not great. The temperature convergence seems better.

Suggests to me this may be a problem with poor convergence criteria/hysteresis, with the collisional cooling change just being the butterfly.

there's also an unresolved drop in both ne and H+ around 8.5×10^{11} cm in the first iteration, which might be worth trying to understand.

Peter: It looks like there is a small thermal front in this model near the outer edge, though I derive this only from eyeballing the Te plot. They are quite common in blr models. It would also be a partial explanation of the jerky behavior of the code: gas near such a front will be quite sensitive to changes in cooling and/or heating since the curves are nearly parallel. It is however still worthwhile asking whether we are exacerbating the problem by writing the cooling terms in atom_leveln() the way we do.

Robin: Yes, there is a temperature front exactly at the rear of the slab (it only appears in the later iterations).

email exchange on this was around 2010 dec 22 - 24

This is the lower density cloud computed in Rees et al. (1989). Table 1 of that paper lists the predictions, which were a mean of those of Hagai Netzer's ION and roughly version 76 of CLOUDY. The lines are generally still in good agreement with the predictions of that paper. In particular the changes in the line fluxes shown in Figure 1 of that paper are reproduced quite well.

This is a very dense cloud, and was computed in Rees et al. (1989). Table 1 of that paper lists the predictions, which were a mean of those of Hagai Netzer's ION and roughly version 76 of CLOUDY. The lines are generally still in good agreement with the predictions of that paper. In particular the changes in the line fluxes shown in Figure 1 of that paper are reproduced quite well. The fluxes of Ly α and H β are not reproduced with great precision by this model because of changes in collision rates for hydrogen and especially the form of the escape probability function for subordinate lines. As Figure 1 of RNF showed the line intensities are very sensitive to density for these parameters.

This tests conditions of collisional equilibrium at low densities. This is one of a series of sims coll_t?.in which test ionization over a range of temperatures. This one, unlike the others, includes cosmic rays. Chemistry is important at this low temperature and the chemical network will collapse without a source of ionization. The cosmic rays provide this source of ionization.

```

This is a model similar in spirit to the blister geometry H+ region model computed by Baldwin et al. (1991), but with a D-critical flow. Many physical processes have been disabled to make this simulation faster. Grain physics is not done so the gas temperature is incorrect. The main purpose is to do a quick test of the dynamical flow with grain opacities included. The slow directory contains a full simulation of a flow like Orion.

# =====
#

```

This tests the radiative acceleration and terminal velocity of a wind in which only electron scattering is important. The parameters were chosen so that electron scattering is the dominant opacity source, so that the equations can be solved both numerically (in the example) and analytically (the expected solution given above). In a realistic wind the gas would be more neutral and line driving would dominate. The force multiplier, given in the save wind output, is nearly unity as a result.

Checks:

- The radiative acceleration is correct ($e-9.543910^{-7}$ cm s⁻²).
- The terminal velocity should be 7.57 km s⁻¹.
- Force multiplier near unity (no line driving since so highly ionized).
- Thickness of cloud correct ($R-R_o + dr/2$ should be 3.086391017 cm).

```

Normally the code predicts the intensity or luminosity of the emission lines. This test confirms that it can predict the flux recieved at the Earth instead. The model is the simplest and fastest that can be computed - a H-only constant temperature single zone. The total luminosity is set to 1e40 erg/s, and the ionization source

is a laser at 2 ryd. With these set, the total luminosity in ionizing radiation, the total luminosity in the incident continuum (the emission line labeled "Inci 0") will be 1e40.

The code will predict the flux at the Earth if both the distance to the object is specified with the distance command, and this is requested with the print flux earth command. The distance was chosen so that the total flux at the Earth will be 1 erg/s. This is asserted at the end of the calculation.

#
# func_grid_line_line_ratios.in
# class function
# =====
```

This uses the grid command to compute line ratios for a wide range of density and temperature. The ionization is set to a uniform value and only a few elements are included. this makes the calculation faster and prevents recombination [O III] 4363 from becoming important (there is no O+3).

These are the line ratios mentioned as limits in the Johnstone et al. Spitzer cooling flow filament paper (2007).

func_grid_list.in

test the 'list' keyword on the grid command

```
title test the 'list' keyword on the grid command
blackbody 10000 STE vary
grid list "func_grid_list.dat" linear sequential
hden 5
stop zone 1
iterate 2
*****
```

This is a simple grid with parameter values stored in an external file. That file is also used to monitor the temperature of each grid point.

func_hotgas_coolstar.in

test very soft continuum, very hot gas

```
title test very soft continuum, very hot gas
#
# commands controlling continuum =====
# put in the cosmic background as the only continuum source

# class limit
# =====
#
```

This test irradiates a set of grains with a true blackbody in strict thermodynamic equilibrium. We expect the grains (and everything else) to equilibrate at the blackbody temperature. The gas temperature is forced to the radiation temperature because the current molecule network (based on ISM approximations) does not go to LTE in the high-radiation density limit. The calculation asserts that all grain temperatures are very close to the radiation temperature.

# class coronal
# =====
#
#*****
```

This is a classical cooling function calculation - cosmic rays must be included for temperatures below 1e4 K to sustain chemistry. This is a coronal (collisional) ionization calculation.

This version uses primordial abundances. A small CR rate has to be set for the low-T chemistry to work. The possibility of primordial cosmic rays is mentioned by 2014A&A...570L...3T although they are not part of standard primordial chemistry networks.

This is not a realistic model for several reasons. First, it uses the approximate small H2 model - the large model invoked with ATOM H2 is better but slower. Second, primordial chemistry is time dependent - the Universe is typically not old enough, at a given z , for the chemistry to have reached steady state. This is a time-steady calculation.

The purpose of the test is to demonstrate code behavior in the metal-free limit, over a wide range of temperature. Gas-phase light-element chemistry is exercised, but with the trace amount of cosmic rays.

# =====

```

This is a collisionally dominated H2 simulation. The temperature has been fixed at 2000K and the large molecule turned on. The calculation checks the returned value of the ortho to para densities. Cosmic rays and the incident continuum have little effect, the density is high, so the populations should be close to LTE.

#

```

This checks that the predicted hydrogen continuum is in good agreement with exact results in the optically thin nebular limit.

Checks:

- This output was used to generate figure h_t4_conemis_thick in Part I of HAZY.
- Continuum relative to Hbeta should agree with Ferland (1980) filter averaged results.
- Hbeta should agree with Case B predictions, and Q(H) 4861.

This is a plane-parallel constant temperature cloud with only hydrogen and helium. The gas has a filling factor of 0.1. Induced processes are turned off and a large H atom is used so that the hydrogen recombination spectrum will be close to Case B. The calculation stops beyond the hydrogen ionization front, because of the stop efrac command (it needs this since this is a constant temperature calculation, so the usual lower-temperature stopping criterion does not apply). The asserts confirm that energy is conserved and that the hydrogen spectrum is correct.

This is one of the test cases from the Lexington Meeting suite of nebulae (Ferland et al. 1995). It is a grain-free hii_blister HII region, similar to inner regions of the Orion Nebula, except for the absence of grains. The set of lines entered with the print line sum command lists the most powerful coolants in this model. This is one of the tabulated quantities in the Lexington Meeting, and is a fundamental test of energy conservation in the code. The ratio of the sum of these lines to H β is equivalent to the Stoy ratio, used for determining stellar temperatures.

The "dielec kludge 0" command is to turn off my estimates of the DR rates for those elements that had none. This was only to allow comparison with other calculations that did not make similar estimates. For an actual calculation I would not include this command, since the guesses are better than nothing.

the turbulence is to stop the balmer lines from becoming optically thick since few other codes include an actual H atom, but use case b instead. The Orion HII region does have an observed turbulence of about 8 km/s.

This calculation stops near the H $^+$ - H0 ionization front, where the temperature falls below the default lowest temperature of 4000 K. This model would have continued into the PDR had a lower temperature been specified with the STOP LOWEST TEMP command.

This is an example of an H II region irradiated by a hard stellar continuum - one of the Mihalas NLTE stars. The hard continuum produces a negative He/H ionization correction factor, as discussed in Ballantyne, Ferland & Martin (2000). >>refer HeI icf by Ballantyne, D.R., Ferland, G.J., & Martin, P.G., 2000, ApJ 536, 773-777

```

This is one of the "standard" models computed at the Paris and Lexington meetings on photoionization and shock calculations. a table in hazy compares the predictions of the current version of CLOUDY with predictions of a few of the other codes. It is necessary to iterate since some fine structure lines are optically thick. The set of lines entered with the print line sum command is used to obtain the total luminosity in detected lines, a measure of the Stoy temperature.

Checks:

- H β close to case B, Q(H) 4861, intensities.
- Enter answers in Table Error! Reference source not found..

This example demonstrates the behavior of the code in the low-density limit.
 The ionizing source is the cosmic background at a redshift of $z = 2$.
 The cloud is assumed to be optically thin to ionizing radiation,
 in keeping with the Gunn-Peterson test, so the double command is included,
 and an iteration is performed to converge the optical depth scale.
 Continuum fluorescent excitation of lines is important because the cloud
 is optically thin.

This sim corrects line intensities for isotropic continua. Its sister sim, `igm_lalpha_noisosub.in`, computes
 intensities uncorrected for isotropic continua.

This is a high redshift cloud irradiated by the cosmic background and AGN light.
 H- absorption of the $z=10$ cosmic background is a MAJOR heating agent
 This model is very sensitive to treatment of Ly α destruction, since resulting
 J-bar is major destruction process for H-, which is the H₂ formation route.
 Ly α oscillations could develop and are damped by not reevaluating H-
 photo rate after first n times, as in hmole.c

TODO - look at temperature struture - it has jitter at about the level of convergence, up and down. Temp jitter caused by eden jitter. This model is nearly isothermal, jitter measures noise in solver, and is great chance to pin this down.

This is a test of the behavior of the code in the extreme of photoionization by a relatively hard continuum, at low densities. The continuum is the galactic background, attenuated by a column density of 10^{22} cm⁻². Ionization by galactic background cosmic rays is included. Database H-like Lyman pumping off appears since this region is deep in the ISM, and the Lyman lines are quite thick. This example checks whether the ionization balance, thermal balance, and electron density sum, are performed correctly in this limit.

Checks:

- Numerical stability of solution
- Thickness exact

this shows an S-curve calculation - make plot showing density as X-axis and gas pressure (nT) as y-axis

the gas is ionized by the galactic background. the density varies between $1\text{e-}3$ and $100\text{ cm-}3$. this is the full range found in the diffuse ism. The components that are produced are CNM - cold neutral medium, density $\sim 40\text{ cm-}3$ WNM - $n \sim 0.5\text{ cm-}3$, WIM - warm ionized medium, $n \sim 0.25\text{ cm-}3$ HIM - hot ionized medium, $n \sim 1\text{e-}3\text{ cm-}3$, calculation DOES NOT reproduce observed temperature of HIM - we get $\sim 1\text{e}4\text{K}$ but observed is $\sim 1\text{e}6\text{ K}$. HIM is shock, not photo, ionized

```

This model generates a large column constant density cloud similar to the hot phase of the interstellar medium. The continuum is punched to generate one of the figures in Part 2 of Hazy.

There is a strange feature between 1.7e-3Å and 2.2e-3Å that is the N emission (head starting at 1.7e-3Å with O absorption at 2.2e-3Å. This model is strongly enriched in heavies so many metal edges, esp O, are optically thick.

>>TODO 1 the guess of the thickness of the first zone is badly too small, because this model is collisionally ionized, and it used Stromgren length - better to use collisional balance and dr - as result of this the model takes far too many zones

# =====
#

```

This example creates the file `ism_opacity.opc` which tabulates the total opacity of the gas as a function of energy. These plots are used in ISM studies to understand the transmission characteristics along a line of sight. The opacity depends on the dust to gas ratio, the gas phase abundances, and the level of ionization, all of which can be changed by altering parameters given above.

The model is of a 1 cm thick parcel of gas which is optically thin in the Lyman continuum and Lyman lines. As a result the hydrogen emission line spectrum is close to case C. The model iterates so that the predicted ionization and emission know about this.

# class limit
# =====
#
```

Case A is a mathematical fiction; when the Lyman lines are optically thin continuum pumping must be important if the gas is ionized. Fluorescence is turned off with the no induced processes command. The density is set to a very high value (10^{15} cm^{-3}) so that the 2s-2p states are well l-mixed, in keeping with standard case A assumptions. As a result, collisional excitation would dominate the level populations, and hydrogen collisions must be turned off with the hydrogen collisions off command. The Ly* optical depth is set to a small value. The set dr command sets the zone thickness to 1 cm. The abundances are set to a very small value so that the electron density is equal to the hydrogen density.

Checks:

- Departure coefficients for H, He levels
- Neutral fractions
- H* emissivity

This is a pure hydrogen cloud that is optically thin in the Lyman continuum. The asserts check the emission in several H I lines and continua. This should be close to what really happens in a low column density cloud exposed to a continuum source that does not have strong Lyman lines. (The continuum source used is a pure blackbody, and so has no lines). So this is an example of "Case C" emission >>refer H case C Ferland, G.J. 1999, PASP, 111, 1524

This tests the code in the low temperature Compton limit. The gas is illuminated by a 3 K blackbody in thermodynamic equilibrium. The equilibrium temperature should be exactly 3 K. It is necessary to add an extra component of free electrons to test the code in this limit with the eden command. If eden is pushed up too high, ee brems cooling will be artificially boosted compared to other cooling terms and start cooling the gas below 3 K. This is why eden was set to 1e-3 cm^{-3} on 20141105.

```

This tests the behavior of the code in the Compton limit. The incident continuum is a blackbody in strict thermodynamic equilibrium. Strict thermodynamic equilibrium is expected for all constituents of the gas. The input stream also lists the expected photon fluxes for the incident continuum; this tests the normalization of the continuum, and its distribution. Grains are included to confirm their behavior in the LTE limit. The set dr command sets the zone thickness to 1 cm.

Checks:

- Luminosity, photon flux, over various energy intervals, 4^*J at 912143.
- Electron temperature exactly 2^*10^5 K.
- Grain temperature forced to 2^*10^5 K by radiative processes.

# =====

```

This checks that energy is limit_conserve. The code always checks that it did not radiate more energy than was absorbed. This calculation extends well past the photo-dissociation zone into fully molecular gas, so that all of the incident radiation is absorbed. Grains, CMB, & CRs are not present so that only the incident radiation field powers the gas.

Small changes can affect this model to surprising extents because of the presence of a major thermal front at the H0 - H+ transition region.

limit_eden.in

Martin Gaskell's funny model

```

title Martin Gaskell's funny model
# used to test that electron density convergence is ok
# hydrogen line spectrum strongly pumped by continuum
# all elements > H have HIGH abundances

```

This is mainly a test of the ability of the code to converge a model with a very strange electron density. The electrons are mainly contributed by heavy elements, and the gas is only slightly ionized.

Ionization of elements Fe, Mg, Si strongly affected by charge transfer with other heavy elements.

Checks:

- Electron density is correct.
- Hydrogen line spectrum strongly pumped by continuum.

This example tests whether induced processes force level populations of hydrogen to LTE when they are irradiated by a blackbody in strict thermodynamic equilibrium. The density is low enough value for radiation to dominate the rate equations coupling levels with each other and the continuum. The expectation is for all departure coefficients to equal unity.

Checks:

- Departure coefficients exactly unity.
- Grain temperatures are exactly 5×10^4 K.

This checks that the model H atom goes to LTE at high densities.

chng 06 aug 24, had not included collisional ionization, and so he-like departure coefficients were very large, around 202. comments said there were problems. turned on collisional ionization, no problems noted

chng 06 jul 22 with RP changes in high-n n-changing collisions the rates are now much smaller - needed to change density to be far higher and several quantities changed. at lower density (10^{18} cm^{-3}) the populations are very unphysical and runaway maser now occurs. this is only a homework problem and intended to only test n-changing collisions. with higher density this test is done.

# =====
#
```

This model is a test of the behavior of hydrogen and helium in the high density, collision dominated, limit. The temperature is preset, the hydrogen density is set to a very high value, and the ionization parameter is very low. The resulting model is collision dominated, so this case checks that the collision physics occurs in detailed balance. The predicted departure coefficients should all equal unity. The set dr command sets the zone thickness to 1 cm.

Checks:

- Hydrogen departure coefficients exactly unity.
- Helium departure coefficients near unity. (Density not high enough to bring helium departure coefficients exactly to unity.)
- H-, H₂, H₂⁺ H₃⁺, and HeH⁺ departure coefficients exactly unity. `

```

This is the ultimate test of the behavior of the code in the strict thermodynamic equilibrium limit. The temperature is not held constant, so the resulting equilibrium temperature determines whether cooling processes are treated properly in the detailed balance limit. The equilibrium temperature should be exactly 5×10^4 K, and all departure coefficients should equal unity. A small amount of grains are included to check that the grain thermal balance is handled properly in this limit.

Checks:

- Electron temperature exactly 5×10^4 K.
- Departure coefficients unity.

```

This is a test of the treatment of the diffuse fields, their transfer, and their effects on the ionization structure of a nebula. The comparison is made against the exact calculation published by Van Blerkom and Hummer (1967). The geometry is open, that is, similar to that assumed in most BLR calculations.

>>refer H ionization Van Blerkom, D., & Hummer, D. G. 1967, MNRAS, 137, 353

The diffuse ots command is entered in order to reproduce the Van Blerkom and Hummer results. The default assumption, outward only, does not agree as well. I changed the default from OTS to outward only to be in better agreement with predictions by Harrington and Rubin at the Lexington meeting. They have not checked whether their codes are in agreement with the Van Blerkom and Hummer paper.

Checks:

- Neutral fraction at illuminated face 5.8×10^{-4} .
- Location of ionization front at 7.8×10^{16} cm.
- $34\text{He } 1\ 486134$ and $34\text{CA B } 486134$ agree; both slightly lower than $34\text{Q(H) } 486134$.
- Answers with OTS agree with 1967 results.

test hydrogen ground state rec effc against vb+h exact results this is their case e) - "zero condition" their answer for $H0/H_{\text{tot}}$ at the illuminated edge is approx $5.8\text{E-}4$, and a Stromgren radius of approximately $7.7\text{E}16$ cm

# =====

```

This is a model similar in spirit to the blister geometry HII region model computed by Baldwin et al. (1991). Size-resolved Orion grains are included. The constant pressure command does a hydrostatic equilibrium structure. The predicted emission-line spectrum is affected by the reddening of the internal grains. The resulting t2 analysis produces artificial results as a result. This has an open geometry, the original BFM paper was a closed geometry. (This makes little difference). Background cosmic rays are also included although these should have little effect on warm ionized gas. The emission line spectrum is given in surface brightness units, as in the BFM paper.

This is a dense ISM exposed to a cool blackbody. This tests the ability to converge onto a VERY molecular environment. Nearly all C and H are in CO and H₂. Cosmic rays are the main source of heat and ionization.

Continuum pumping of CO followed by collisional deexcitation is a major heating agent across the sim.

This is the Hollenbach et al 1991 Low-density PDR The Database H-like Lyman pumping off command appears because the Lyman lines are vastly optically thick in this environment. If the command is removed the Lyman lines will be optically thin, which will result in fast fluorescent excitation of the (nearly totally neutral) hydrogen atom.

there is very little CO in this model since it is not thick enough for the UV pumping lines to become optically thick

# CONDITIONS IN ZONE 1 AND 2 ARE IN VERY GOOD AGREEMENT!
#
# pdr_minimal.in
# class pdr
# =====

```

This model is derived from the F4 model from the Leiden workshop (Roellig et al. 2007, A&A, 467, 187). It has been reduced to a two-zone model in order to test the ionization conditions at the face of the PDR. Older versions of the code had a bug where the ionization in zone 1 was many dex lower than in zone 2. The conditions in zone 1 were wrong and should have been similar to the conditions in zone 2. Here we test that the code doesn't regress. See also ticket #358: <https://wiki.nublado.org/ticket/358>

The ionization in this sim is produced by continuum pumping of the metastable levels of N I, followed by photoionization out of the metastable levels of N I. See Ferland et al., 2012, ApJ, 757, 79. So this pumping and ionization mechanism is also tested by this sim.

This is the Tielens and Hollenbach (1985a, b) standard model of the Orion photodissociation region (PDR). Specifically, this is my attempt at their Table 2 of paper 2, ApJ 291, p749. The Database H-like Lyman pumping off command appears because the Lyman lines are vastly optically thick in this environment. If the command is removed the Lyman lines will be optically thin, which will result in fast fluorescent excitation of the (nearly totally neutral) hydrogen atom.

This is one of the "standard" models computed at the Paris meeting on photoionization and shock calculations. A table in Hazy compares the predictions of the current version of CLOUDY with predictions of a few of the other codes.

The model is meant to represent a planetary nebula ionized by a very hot central object. As a result there is a great deal of He⁺⁺ and the associated line and continuum emission is very important.

An age of 10000 years was set. This tests logic in the age command.

```

Test time dependent cooling at constant density. In time_cool_cd.in, the line emission accumulation is done by default by mass. In this sim, no accumulation is performed (see 'set cumulative' above). The final line fluxes are those of the last iteration. This sim is meant simply to exercise the 'set cumulative off' command, so a full run to low temperatures is deemed unnecessary.

D.4 The Slow Test Suite

Table D.3 lists the simulations in the `slow` test directory.

Table D.3: The simulations in the slow test suite.

Class	Function

```

This is the Hollenbach et al 1991 Low-density PDR The Database H-like Lyman pumping off command appears because the Lyman lines are vastly optically thick in this environment. If the command is removed the Lyman lines will be optically thin, which will result in fast fluorescent excitation of the (nearly totally neutral) hydrogen atom.

there is very little CO in this model since it is not thick enough for the UV pumping lines to become optically thick

05 dec 19, had stopped at 1 pc, gas/dust got very cold and H2 stopped forming, H2 went to H0 - this below the CO network out of the water. stop at AV of 1000 instead. Is this loss of H2 at low grain temperature physical? Is it ever seen?

This is the Tielens and Hollenbach (1985a, b) standard model of the Orion photodissociation region (PDR). Specifically, this is my attempt at their Table 2 of paper 2, ApJ 291, p749. The Database H-like Lyman pumping off command appears because the Lyman lines are vastly optically thick in this environment. If the command is removed the Lyman lines will be optically thin, which will result in fast fluorescent excitation of the (nearly totally neutral) hydrogen atom.

>>refer model pdr Tielens, A. G. G. M., & Hollenbach, D. 1985a, ApJ, 291, 722 # >>refer model pdr Tielens, A. G. G. M., & Hollenbach, D. 1985b, ApJ, 291, 746

```

Similar to orion_hii_pdr except for plane parallel geometry. The properties of the molecular region change when details of the H⁺ region change because the pressure of the entire cloud can change as a result. The goal of this sim is an existence proof - that it can be done, rather than the stable details of the molecular region.
